All communications to be addressed to the Branch Manager, BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.
Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Peptalac REGD.
THE NEW INSTANT PREDIGESTED FOOD

Predigestion of starch *and* milk is guaranteed and is effected under the most exact scientific conditions in our laboratories before powdering. This means that when required for use it can be immediately and simply prepared by the *mere* addition of hot water. The C. & G. Improved Roller Process is used ensuring retention of the full mineral and vitamin content with freedom from pathogenic organisms.

PEPTALAC is indicated in all those cases where the powers of the digestive tract are insufficient to deal with that amount of food necessary for maintaining health—for nursing mothers with weak digestions, in ante- and post-operative surgical cases, in achlorhydria, peptic ulceration, cancer of the alimentary tract, in all forms of convalescence and in old age.

HEPATEX
WITH IRON

For cases of stubborn Secondary Anaemia

This combination is most effective when a specially powerful stimulation of the blood regenerating organs is desirable. In the treatment of the Secondary Anaemias it is much superior to Liver alone or the ordinary iron preparations. It is readily assimilated and does not give rise to disagreeable after-effects. A small dosage suffices, one fluid drachm containing one grain of iron and the equivalent of 2 ozs. of fresh liver.

Issued in 2 oz. bottles.

Prepared at Evans' Biological Institute, Runcorn.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

NEW SAUNDERS BOOKS

KAPLAN'S RADIATION THERAPY

This new book is practical from beginning to end. It records the great store of first-hand information gained by Dr. Kaplan at the largest municipal hospital in the United States. Here Dr. Kaplan receives annually 2,000 or more cases to be treated by some form of radiation therapy. This is the only modern work in English. Dr. Kaplan devotes his entire book to stating briefly the established principles of the treatment and then detailing extensively the application of these principles to cases. He explains those methods which he has found resultful in treating thousands of patients. He gives the technique he uses; he sounds warning notes; and he gives an Index of Diseases and their Treatment wherein are stated for quick reference the dosage, frequency, precautions, care as applied to individual diseases.

Octavo of 354 pages, with 227 illustrations. By IRA I. KAPLAN, M.D., Director, Division of Cancer, Department of Hospitals, New York City. With a special chapter on *Applied X-ray Physics*, by CARL B. BRAESTRUP, B.Sc., P.E., Radiation Physicist, Division of Cancer, Department of Hospitals, New York City. Cloth, 27s. 6d. net.

WEBSTER'S LEGAL MEDICINE

Dr. Webster has included all legal aspects of medicine, all those problems which reach courts of law and which concern physicians, attorneys, jurists, district attorneys, life, health and accident insurance adjusters. Causes of death, the identity of the living and the dead, the results of wounds and injuries of all kinds, life and accident insurance, mental incompetence from various sources, malingering, legitimacy, abortion and infanticide, impotence, sterility, unnatural sexual offences, marriage, divorce, malpractice are a few of the subjects here presented with authority. There is a large section on Toxicology.

Octavo of 862 pages, illustrated. By RALPH W. WEBSTER, M.D., Clinical Professor of Medicine (Medical Jurisprudence), Rush Medical College, Chicago. Cloth, 37s. 6d. net.

CURTIS' GYNECOLOGY

Dr. Curtis gives first a thorough presentation of infectious processes: Then he presents a study of tumors of the uterus and of the ovary, displacements, relaxations and disturbances of function. Following this are two large divisions devoted to gynecologic diseases and symptom-complexes. Diagnostic procedures and technique are described in detail. There are indications for therapy, special considerations, non-surgical methods, surgical technique, radiotherapy, diathermy, and after-treatment. The final section of the book discusses history-taking and examination, appendix and urinary tract in their relations to gynecology; spinal anesthesia; dietetic considerations; transfusion. Most of the 222 illustrations are the work of Tom Jones.

Octavo volume of 380 pages, with 222 illustrations. By ARTHUR H. CURTIS, M.D., Professor and Head of the Department of Obstetrics and Gynecology, Northwestern University Medical School. Cloth, 24s. net.

ANDREWS' SKIN DISEASES

Dr. Andrews draws sharp, clinical word-pictures. He sweeps away the usual diagnostic difficulties. He interprets signs and symptoms. He leaves nothing untold. He tells you how to select the proper method, how to apply it. He explains the principles underlying the treatment. He tells you how to manage the case. He gives you internal therapy as well as local treatment. He gives you formulas for powders, lotions, salves, ointments, and literally hundreds of prescriptions lifted from his own practice. He details dietetic measures, giving menus, recipes, foods to be avoided as well as those to be taken. The sections on X-ray Therapy, Supersoft X-rays (W-rays, Grenz-rays), Radium Therapy, Ultra-violet Light, and Surgical Diathermy, covering 150 pages, are complete and practical.

Octavo volume of 1,095 pages, with 988 illustrations. By GEORGE C. ANDREWS, M.D., Associate Professor of Dermatology, College of Physicians and Surgeons (Columbia University), New York City. Cloth, 55s. net.

CECIL'S MEDICINE

For this brand new edition the entire book had to be reset, because the 135 eminent contributors were given *carte blanche* in the revision of their articles. The new (2nd) edition represents to-day's approved practice. In addition to the hundreds of changes throughout the book, there are entirely new chapters on tularemia, snake venom poisoning, atelectasis of the lungs, creeping eruption, oroya fever, brucella abortus infections, essential hypertension, agranulocytic angina, and arthritis. In his selection of authors, Dr. Cecil was particularly fortunate. Most of them are teachers in medical schools, and their authoritative presentations are in a form specially acceptable to all those interested in the study and application of medical knowledge.

By 135 American Authors. Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical School. Octavo of 1,592 pages, illustrated. Cloth, 40s. net.

THE METABOLISM OF TUMOURS

Investigations from the Kaiser Wilhelm Institute for Biology, Berlin-Dahlem

Edited by

OTTO WARBURG

Lancet:—". . . the translation is excellent, and the English edition will make a strong appeal to all those who wish to use the manometric technique in the study of chemical reactions, since its theory and practice are described in great detail."

British Medical Journal:—"The researches have added an important detail to our knowledge of the peculiar features of tumour growth—a valuable acquisition, since it opens up a new avenue of approach in the study of the causation of tumours."

Translated by FRANK DICKENS, M.A., Ph.D.

SCARCELY MORE THAN TWICE THE PRICE

of ordinary window-glass

The question of cost has often proved an obstacle against the acceptance of new methods. Before a steady demand had been created for "Vita" Glass prices were necessarily high.

But the new stabilised prices open up vast possibilities for the use of windows that admit health as well as light. "Vita" Glass now costs scarcely more than twice the price of ordinary window-glass but it converts windows into channels of health instead of shutters against it. Its properties are guaranteed permanent. Over 300 hospitals and nearly 200 schools are now fitted with "Vita" Glass. Employers are using it more and more in offices and factories and it is being fitted daily in private houses all over the country. Write for full particulars to the "Vita" Glass Marketing Board, 9 Crown Glass Works, St. Helens, Lancashire.

"Vita" Glass is obtainable through local Glass Merchants, Plumbers, Glaziers and Builders

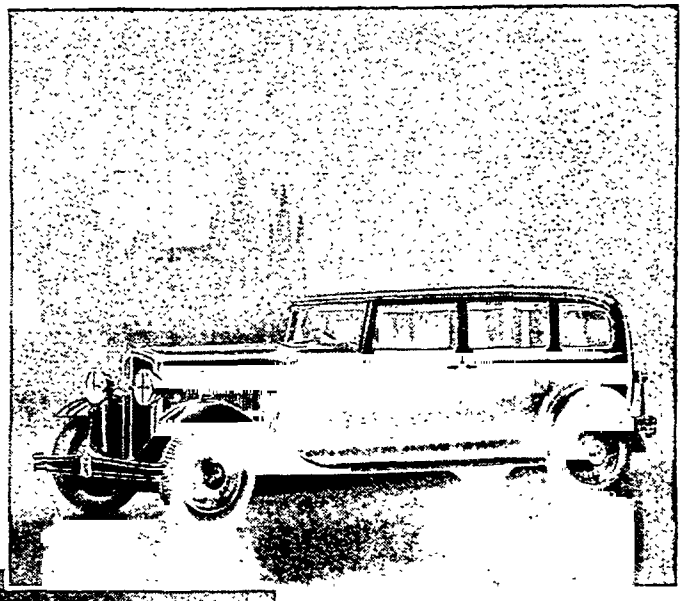
"VITA" GLASS

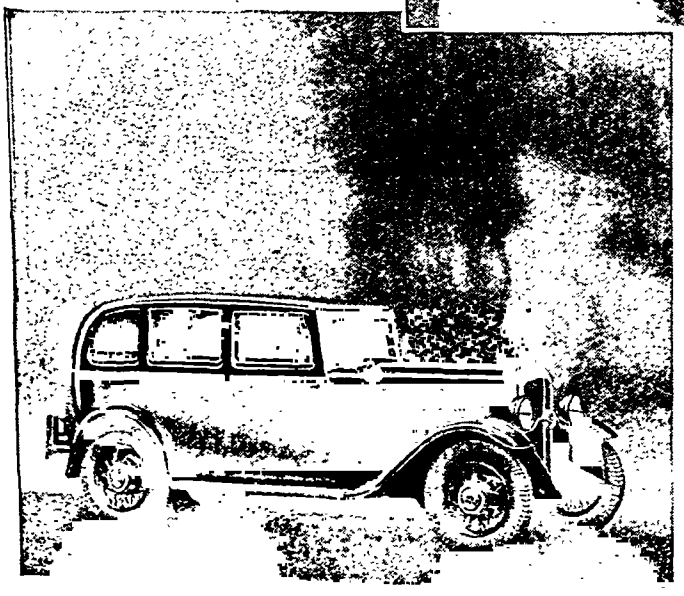
V.318

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

Rover offer a range of cars for every phase of medical service

FROM the distinguished Meteor Limousine to the popular Rover Family Ten there is a Rover model that can, and does, serve every phase of a doctor's duties. The Limousine for the Consultant, securing privacy for the conference en route with colleagues: the Two Litre Six or Light Twenty for the scattered and difficult country districts: the Family Ten for easy manipulation in mean and narrow city streets and in congested traffic—and in each power grade a matchless performance.





WE illustrate two models. The top one is the Meteor Limousine—it has a drop down division that can be closed for professional purposes and opened on social occasions. It costs only £548 and gives dignity, power, and comfort at extremely low cost. The illustration left is the Rover Family Ten offering exceptional passenger accommodation, well sprung and comfortable so that an emergency run with patients requiring almost 'stretcher' length can be easily arranged. It will achieve 60 miles per hour, has run 2,147·2 miles for £5 under official observation. Brief particulars of the price are supplied on the left.

Rover Family Ten—from £189 | Rover Light Twenty—from £358

Rover Two Litre—from £298 | Rover Meteor—from £398

Rover Meteor Limousine £548

NERON VITALUX

The Sunlight Generator

HEAT, LIGHT, ULTRA-VIOLET

The discovery of U.-V. Glass "A" with the highest degree of permeability of all glasses permeable to U.-V. Rays has resulted in the production of a NEW LAMP giving a radiation equivalent to natural July Sunlight.

An indication as to some of its uses:

Rachitis prophylaxis, tubercular cervical glands, surgical and cutaneous tuberculosis, neuralgia, rheumatism (neuritis, myalgia), catarrhal diseases (colds), inflammation of the lungs (pleurisy), treatment of wounds, etc.

Extract from letter recently received from a doctor:
"The lamp is giving me thorough satisfaction, being a great improvement on the carbon arc lamp I was using, owing to the absence of fumes and greater ease of working, as well as giving a more satisfactory spectrum."

A SUSPENSION MODEL is available for Group treatment. Plans prepared free of cost for Hospital Sun Rooms.

NERON VITALUX LAMPS ARE BEING INSTALLED IN VARIOUS HOSPITALS, Etc.

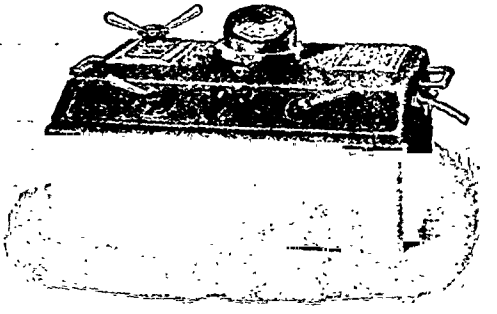
A NEW SURGICAL DIATHERMY UNIT

(ELECTRO-SURGERY)

The introduction of the New Surgical Models of Siemens Thermoflux Diathermy Apparatus permits of hitherto unattainable success in certain operations.
Haemorrhage is minimised.
Post-operative pain and metastasis reduced.
The largest and smallest surgical operations are possible with a Thermoflux Unit.

May we demonstrate to you how it is possible in one machine to control with simplicity the cutting current for every variety of tissue?

Ask for a copy of a new brochure with technical data now in the press, free to all surgeons.



There is a Thermoflux Diathermy Unit for every surgical and medical purpose.

Surgical: Thermoflux A, for small operations, £30; K, high power portable, £55; M, for major operations, £80.

Combined Surgical and Medical Diathermy: Thermoflux C.K, a powerful portable unit for all-round purposes, £40.

Special Medical Units: Thermoflux C, £37 10s.; D2, £47 10s.; D4, £50 (treats 4 patients simultaneously); G, high power unit, 4 circuits, £85.

RECENT INSTALLATIONS INCLUDE—
ST. THOMAS'S HOSPITAL, ST. GEORGE'S HOSPITAL, MIDDLESEX HOSPITAL, BRITISH RED CROSS CLINICS, Etc.

The I·XL STAINLESS STEEL

PHYSICIAN'S POCKET KNIFE

A pleasure to own and delightful to use.

Polished Buffalo Horn Handle

4/-

Each

No 7222.—*This is a Knife we have made for nearly 100 years. Its description appears in one of our old pattern books dated 1858, and was probably copied from an older one.*

ORIGINALLY designed for the Physician, this knife, by virtue of its long, useful, highly polished blade, now made of Stainless Steel, is to-day being used most extensively as a Fruit Knife—in fact, no better knife could be found for this purpose. It is also most useful for opening letters, cutting the leaves of a book, sharpening pencils, and many more purposes which a good knife can serve. The Nickel Silver cap on the end can be used on sealing-wax, or for pressing down tobacco in the pipe. The Physician will still find the long blade of this knife extremely useful for its original purpose—that of taking powder from broad-necked bottles.

There is an I·XL stockist in every district, but as this is a knife designed mainly for Physicians, and there is not a large sale, we are not asking our dealers to stock it.

If you wish for one of the knives, send us Postal Order for 4/-, and we will send it to you through our local dealer.

Before buying Cutlery, fill in the Coupon, place a halfpenny stamp on the envelope and post to-day. →

OUR GUARANTEE

We are sure you will like the knife, but if for any reason you are not entirely satisfied, please return the knife to us within 7 days, and we will promptly refund your money in full.

To GEORGE WOSTENHOLM & SON Ltd., 105, WELLINGTON STREET, SHEFFIELD. Please send me free of charge your new 28-page Catalogue of the celebrated I·XL Cutlery, illustrating and describing a wide range of Pocket Knives, Table Knives, Razors, Scissors, Carvers, and the wonderful I·XL Saw-edged Bread, Salad and Grape Fruit Knives, with the name of the Dealer in my district who sells I·XL Cutlery.

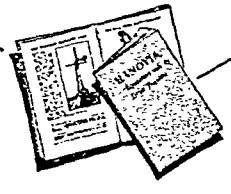
THE SOLLUX LAMPS for luminous heat therapy. Also frequently used in conjunction with Hanovia Quartz Lamps.



Send for this TO-DAY

THE new prospectus issued by the Hanovia Company on equipment for light therapy is a most up-to-date and complete catalogue on the subject.

In its pages will be found a detailed presentation covering the full range of equipment for light therapy—32 pages of descriptive matter.

In addition to the fullest description of this comprehensive range, details will be found of the Reference Library containing reports, papers, and text-books now in the Company's possession. (A free distribution of over 100 reprints listed under their appropriate headings is also offered for the use of the Medical Profession.)

For those not already familiar with actinotherapy, a short outline of its history and scope has been drawn up, followed by quotations from representative opinions on the subject. The book concludes with a full description of the general service rendered by the Company to the Medical Profession.

In view of the growing importance of actinotherapy, you should not be without this new free book. A copy will be sent to you upon request to the address below. Enquiries should be marked Dept. 9.

IN THE POST-INFLUENZAL STATE . . .

BY APPOINTMENT

these essences supply energy—prepare patients for solid diet

In all states of exhaustion, particularly when the patient's recovery is retarded by anorexia, Brand's Essences of Beef or Chicken supply energy and stimulate the system without strain to the digestive organs.

Scientific tests have shown that these essences are assimilated forty minutes quicker than ordinary foods and without the formation of residue. Suave and non-irritant in action, they can be safely recommended in all cases of intestinal disturbances, in specific fevers and in all disorders associated with pyrexia. Before and after operations and in convalescence they are indispensable.

99 out of every 100 doctors recently interviewed recommend Brand's Essences of Beef or Chicken to their patients.

Hygienically prepared from the finest freshly killed English meats by an exclusive process, they are entirely void of preservatives or colouring matter and are deliciously palatable and easy to swallow.

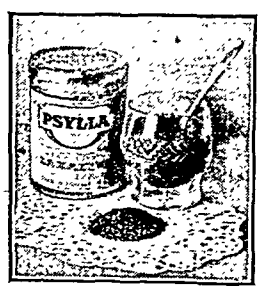
Samples will be sent on receipt of a professional card.—Brand & Co. Ltd., Dept. F.23, Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S

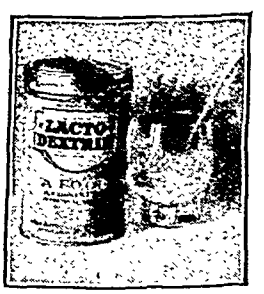
ESSENCES OF BEEF OR CHICKEN

TWO NEW PREPARATIONS

Vide THE LANCET, Jan. 10th, 1931.



"PSYLLA (psyllium) seed; LACTO-DEXTRIN (Battle Creek Food Company, Mich., U.S.A., Distributing Agents, Coates & Cooper, 41, Great Tower Street, London).—This company have sent us specimens of their laxative agent, Psylla, and their preparation, Lacto-Dextrin, for use in intestinal toxaemia. Psyllium seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in Fissure or Haemorrhoids. The same firm has received favourable reports from the clinical use of their combination of lactose and dextrin."—*Lancet*, Jan. 10th, 1931.



Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

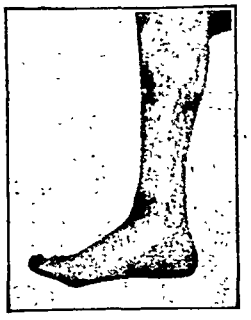
HULL, LONDON, MANCHESTER, GLASGOW.

London Office: 42, TAVISTOCK SQ., W.C.1.
Obtainable through all Surgical Supply Houses.

Photograph shows Ulcer of 25 years' duration. Woman patient. Age 63.



After 18 weeks' ambulatory treatment with Elastoplast applications. Bandages used—15.

For the Treatment of

Pernicious Anaemia

As a result of the discovery that the administration of stomach tissue produces a rapid remission in pernicious anaemia, the need has arisen for a reliable desiccated stomach preparation suitable for human administration.

The issue of Gaster Siccata B.D.H. supplies this need. Gaster Siccata B.D.H. is entirely British, and it bears the B.D.H. guarantee of purity and therapeutic activity; moreover, it is simple in use and practically tasteless.

It is issued in neatly-packed aluminium tubes (each containing 10 grams) in boxes of 3 and of 6 tubes at 4/6 and 9/- per box respectively.

Announcing the issue of

Gaster Siccata B.D.H.

Sanatogen Strengthens but does not Irritate

The value of Sanatogen as a tonic food lies in its ready absorption. Even the weakest stomach can easily digest Sanatogen. For this reason Prof. Ewald of Berlin University, amongst others, has frequently given it in typhoid fever and reports that it is promptly absorbed during the febrile period with apparently the same ease as under normal conditions.

Writing in *"The Medical Press and Circular,"* a leading authority says:

"Sanatogen is readily absorbed by the stomach and has an immediate and remarkable effect, shown by a steady increase of body-weight and of muscular strength and energy."

a Physician writes re....

FLATULENCE AFTER TEA

Copy of M.0208.

"Since you brought 'Ty.phoo' tea to my notice I have drunk no other kind, and I know that I have no flatulence now.

I have prescribed it to my **dyspeptic patients,** who all find benefit from its use."

WE print here one of the many Medical testimonials we are constantly receiving as to the undoubted value to dyspeptics of the pure natural "leaf-edge" tea in which we specialise.

Ask Sumner's Ty.phoo Tea Ltd., Dept. B/MD, Birmingham,

for a free sample of "Ty.phoo" natural leaf-edge tea and full particulars.

TRY "Ty.phoo" TEA in Indigestion.

The Reason Why

Magnesia-Oil (Musterole Brand) escapes every disadvantage of ordinary Laxatives—from uncertainty of action to irritation is because it is an *intimate* association of the Purest Magnesia, with Pure Liquid Paraffin in an almost incredible state of Ultra-Superfine Division—which state greatly magnifies therapeutic action and excludes all undesirable secondary effects.

ITS POINTS

On the Negative Side

It doesn't "leak"
It doesn't "repeat"
It doesn't "irritate"
It doesn't form Concretions
It doesn't deteriorate
It doesn't form a Drug-habit
It doesn't cause distension

On the Positive Side

It corrects acidity
It adsorbs Toxins
It softens the Faeces
It empties the Colon
It rests the Bowel Muscles
It suits Patients of all ages
It is pleasant to take

Chief Indications—

CONSTIPATION of Pregnancy, Infancy and Age
FLATULENCE.....ACID ERUCTATIONS
NAUSEA.....VOMITING
HYPEREMESIS.....TOXÆMIAS
HYPERACIDITY.....DYSPEPSIA
SIMPLE AND ULCERATIVE COLITIS, ETC.

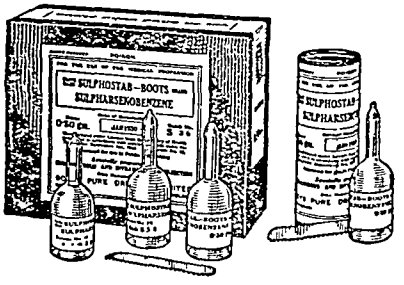
DIOXYDIAMINOARSENOBENZOL SODIUM FORMALDEHYDE BISULPHITE

SPECIALLY prepared for subcutaneous and intramuscular injection in the treatment of Syphilis and other spirochætal diseases. It is practically painless in use, and its high therapeutic activity has been fully demonstrated. Exhaustive clinical trials, both with children and adults, have proved highly satisfactory. **Approved by the Ministry of Health** for use in Public Institutions. Manufactured under Licence No. 19 and biologically tested under approved arrangements.

Obtainable in hermetically-sealed ampoules in the following doses:

0·025 gm. 0·050 gm.
0·075 gm. 0·10 gm.
0·15 gm. 0·20 gm.
0·30 gm. 0·45 gm.
0·60 gm.

Supplied in single ampoules or in boxes of ten ampoules.



R AND C

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Influenza and Capillary Tone

Another influenza epidemic finds us still without a specific preventive or a specific remedy. Fortunately, both the incidence and the course of the disease can be favourably modified by the observance of such rules as medical experience teaches.

It is essential to maintain vigorous metabolism and healthy capillary tone, whilst avoiding undue cold and damp. Adequate stimulation of the sensory nerve-fibrils of the skin, also, is of supreme importance in keeping the body's resisting power at its highest, and in increasing its recovery-capacity. For these purposes THERMOGENE has been found by many medical men and their patients to be convenient, cleanly and effective.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

THERMOGENE

MEDICATED WADDING

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamilar with Thermogene and its many uses in practice.

The Thermogene Co., Ltd., Queen's Road, Hayward's Heath, Sussex.

HORLICK'S MALTED MILK

A VALUABLE ADDITION to a diet at any time—especially so during the winter months. At this season of the year, the lack of stamina and diminished resistance to infection, so closely related to errors in nutrition, most conspicuously manifest themselves. It is therefore, all the more necessary that care should be taken to ensure that patients shall be given a diet which will satisfy their energy needs, lessen fatigue, prevent tissue waste and build up a reserve. HORLICK'S, a well-balanced food, with its easily digested protein, its readily assimilated fat and mixed carbohydrate—lactose, maltose and dextrin, and adequate vitamin content, promotes physical and mental fitness, increases resistance to infection and restores vitality. To combat Influenza, Pneumonia and other complaints so common in winter, HORLICK'S can be prescribed with confidence.

EVANS' THROAT Pastilles

MADE BY

EVANS SONS LESCHER & WEBB Ltd.

56, Hanover Street, LIVERPOOL and LONDON

THROAT THERAPY.

Evans' Pastilles are prepared to a formula of the Liverpool Throat Hospital. Their action is soothing and demulcent, the formula being carefully balanced with both these objects in view. Evans' Pastilles relieve harshness and irritation and maintain their effect for some time after the pastille has dissolved.

Sold in 1/- tins or in bulk for dispensing.

A physician's sample will be gladly sent on request.

The beneficial effects of physical therapy in the rheumatic group of diseases are due mainly to influence on circulation, particularly on the capillary beds.

ANTIPHLOGISTINE

Neuritis and Fibrositis

dressings are very valuable in the treatment of neuritis and fibrositis in the neighborhood of the brachial and cervical plexuses. ■ They have the great advantage of supplying continuous moist heat, and they can be easily molded to the affected part. ■ Intensive hyperæmia can thus be produced at any particular spot with all its beneficial effects.

when you forbid a patient caffein please hasten to add—

When a patient's face falls at your order to avoid caffein, please hasten to add a word of cheer.

Console the patient with the fact that, in forbidding caffein, you are not forbidding the satisfying flavour of coffee. Remind the patient that he can still drink H.A.G. Coffee—genuine, delicious coffee with the effects of caffein minimized.

There is, however, another reason besides your own benevolence for recommending H.A.G. Coffee. By letting your patient enjoy the rich and satisfying flavour of H.A.G. Coffee, you remove all temptation to drink caffein-containing coffee on the sly.

Rich in flavour—tempting in aroma

H.A.G. Coffee is real coffee—a superior blend of the choicest Central and South American coffees. The decaffeination process takes place *before* the coffee beans are roasted. This leaves intact all the mellow flavour and fragrance that make coffee "the beloved beverage." Coffee experts recognise that no other blend is finer.

H.A.G. Coffee is under the Independent Control of The Institute of Hygiene and British Analytical Control.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Some Observations of the Action of Caffein," a more complete discussion of H.A.G. Coffee. Send the coupon now.

THE TUBERCULOSIS DANGER!

It has been stated in Parliament that *over two thousand children die every year through tuberculous milk.* How many children who survive grow up weaklings through the taint of bovine tuberculosis? This hardly bears thinking about. Cow & Gate Milk Food is guaranteed absolutely free from tuberculosis and other pathogenic organisms.

Read the following extract from the Presidential Address at the Royal Sanitary Institute Congress at Margate, it is of vital significance to the medical and nursing professions:

'The loss on the agricultural and veterinary side of 52,222 bovines during the three years 1926, 1927, 1928, slaughtered under the Tuberculosis Order of 1925, and at least twice that number not reported but otherwise disposed of, the estimate that 40 per cent. of the cows of our dairy herds producing milk for human consumption are tuberculous, are circumstances in themselves that demand immediate attention. But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended. It is no credit to us as scientists and protectors of public health that such a state of affairs should be permitted to continue, or even to exist.'

-IS SAFE!

Another remark made at the meeting was as follows:

'It would be better to have no milk supplied at all than to feed children on diseased milk as is being done at present.'

Cow & Gate Milk Food

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins unimpaired. It is a basic milk food which can be modified by the profession as they desire to suit each and every case.

WRITE FOR PARTICULARS OF OUR SPECIAL MILK FOODS FOR DIFFICULT INFANT CASES

Dept. 20 COW & GATE LTD., GUILDFORD, SURREY

MEASLES
and
WHOOPING COUGH

The danger of these disorders is often in their far-reaching secondary effects.

During Convalescence from Measles there is a very special liability to tuberculosis invasion, many victims subsequently succumbing to Tuberculosis, Broncho-Pneumonia or Surgical Tuberculosis, and there is the same liability to Broncho-Pneumonia from Whooping Cough.

Virol is composed of Bone Marrow, Glycerine Extract of Red Bone Marrow, Malt Extract, Eggs, Lemon Syrup and Salts of Lime and Iron.

The Vitamins are present in Virol in its manufactured state.

Phagocytosis

The raising of the patient's powers of resistance is therefore important. Virol has been proved to increase the phagocytosic action of the leucocytes against the germs of Tuberculosis.

The convalescent stage calls for special reparative nutrition. Virol has a marked effect upon the conservation of the tissues, repairing the waste and restoring the equilibrium of a healthy metabolism.

VIROL

More than 3,000 Hospitals, Sanatoria, and Infant Clinics use Virol regularly.

Introduction to the Medical Profession of

REG. TRADE MARK

Feen-a-mint

The Chewing Laxative

In these days when the number of remedies for constipation is legion, and when almost the whole field of materia medica has been explored, some justification is necessary for bringing yet another laxative to the notice of the Medical Profession.

The laxative is Feen-a-mint, and it carries its own justification—as a trial will readily and most satisfactorily demonstrate.

Feen-a-mint is added to the therapeusis of constipation because it embraces the very desiderata of treatment often lacking in many so-called remedies.

The composition of Feen-a-mint is simple (the active principle being the well-known phenolphthalein but its *presentation* is a matter of great importance, and one which secures very complete therapeutic results.

In Feen-a-mint, phenolphthalein — in a state of remarkably fine division—is incorporated into a resinous gum base.

This product is intended for thorough mastication by the patient—which further aids sub-division and even distribution on the walls and contents of the intestine, with resulting peristaltic waves—free from griping and without irritation to the intestinal or urinary tracts.

The defæcation from Feen-a-mint is easy and satisfactory, whilst the re-action is the comfort arising from a completely emptied colon.

In a word—Feen-a-mint is the Ideal Laxative because it really ensures evacuation without secondary effects of any kind. It is very agreeable to the palate.

INDICATIONS

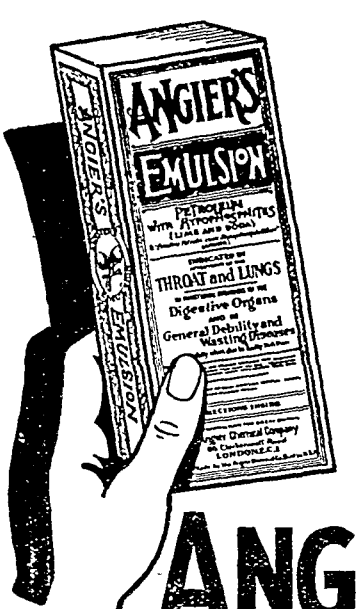
CONSTIPATION of all types at all ages. As an eliminant of toxins in pregnancy where other anti-constipative measures have failed.

Prescribing Note :—Feen-a-mint is not therapeutically incompatible with any drug or treatment, and further it is not absorbed.

★ SAMPLE OFFER—*Free of all charge or obligation, clinical samples will be sent on request.*

FEEN-A-MINT PRODUCTS LTD., 1 BUSH HOUSE, LONDON, W.C.2

FOR CHILDREN IN BRONCHITIS, WHOOPING COUGH, MEASLES & SCARLET FEVER



Angier's Emulsion is one of the most useful and dependable remedies at the command of the physician for the treatment of the various inflammatory and bacterial affections of children. Its soothing, inflammation-allaying properties and its general tonic effects are of first importance in these ailments, while its pleasant, cream-like flavour and ready miscibility with milk make it easy of administration even to the youngest infants.

In many of the wasting diseases of childhood a sensitive irritable stomach and intestines preclude proper nourishment. Under the administration of Angier's Emulsion these organs become pacified and retentive, digestion is strengthened, and the assimilation of food is normal and complete. We confidently urge its trial in marasmus, scrofulosis, inherited tuberculosis, anæmia, and in the malnutrition associated with acute infectious disease.

(MARTINDALE—Regd. T.M. & Design)

IN BOXES OF 12 "STERULES"

Containing 1, 2, 3, 4, 5, 6, or 10 minims (0.05, 0.1, 0.2, 0.25, 0.3, 0.35, or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving ANGINA PECTORIS, SPASMODIC ASTHMA, MIGRAINE, POST-PARTUM HAEMORRHAGE, HAEMOPTYSIS, to ward off EPILEPTIC ATTACKS, etc., and as an ANTIDOTE to CHLOROFORM. Largely employed in threatened FAINTING and COLLAPSE, and as a RESTORATIVE after GAS in DENTAL OPERATIONS.

Abstracts from the medical literature:

ANGINA PECTORIS: "The best remedy. To lower blood pressure has a more rapid action than any other drug, and is useful in cutting short the paroxysms of pain." —L., ii/05, 325; ii/06, 1255.
"Gave prompt relief in the more pronounced attacks." —B.M.J., ii/06, 304.
"In all spasmodic affections, such as angina pectoris, one of the best remedies."—B.M.J., i/09, 934.
"The nitrites are indispensable."—B.M.J., ii/09, 1122.
"The quickest means of relieving the acute pains." —L., ii/08, 1132.
"Fear of death entirely disappeared."—L., ii/09, 572.
"No drug can compare with Amyl Nitrite."—L., i/09, 240; L., ii/05, 812.

INTRATHORACIC ANEURISM: "For the acute anginal attacks Amyl Nitrite inhalation, followed by internal use of Nitroglycerin or Erythrol Nitrate, is generally efficacious."—L., i/13, 948.

ASTHMA: "In most cases the reduction in blood pressure relieves."—B.M.J., ii/11, 1327.

POST-PARTUM HAEMORRHAGE: "Immediately stopped; no further trouble followed."—B.M.J., ii/06, 1125.

HAEMOPTYSIS: "With few exceptions, promptly effective. Secures peace of mind to sufferers." —L., i/08, 130.
"Some convincing cases in which it saved life." —L., i/07, 939.
"Amyl Nitrite the drug par excellence: acts better the quicker it is used."—Edin. Med. JT., 1904; L., ii/04, 522, 942, 1446; B.M.J.E., i/06, 79.
"In severe haemoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory."—B.M.J., i/06, 917.

SEA-SICKNESS: Very useful; inhalation repeated every 2 or 3 hours if necessary.

CHLOROFORM SYNCOPE: The quickest means of restoring the heart's action.

Observations
ON
MORTALITY IN ACUTE APPENDICULAR DISEASE*

BY
D. P. D. WILKIE, M.Ch., F.R.C.S.
PROFESSOR OF SURGERY, UNIVERSITY OF EDINBURGH

I make no apology for taking up a subject which has been dealt with repeatedly in recent years. We are faced with the fact that despite improved education, the greater appreciation by the public of the dangers of the disease, the extended hospital facilities, the vastly improved transport service, and the increased number of capable operating surgeons, the death rate in acute appendicular disease is as high to-day as it was twenty years ago. There can be no doubt that early operation is now practised the country over to a degree greatly exceeding that of two decades ago. How are we, then, to reconcile our advocacy of early operation with this persistently high mortality? To my mind the explanation is clear, and permits of no doubt—namely, that the majority of the patients now operated on early are of the class which did not contribute to the mortality, while in the dangerous and fatal type of case operation occurs little, if at all, earlier than it occurred twenty years ago.

Why is it that this type escapes early diagnosis and thus early operation? It is here that I join issue with the teachers of pathology and of surgery. The fundamental facts of the pathology of the acute diseases of the appendix are not presented to-day, either in the textbooks or, so far as I can gather, in lectures, with greater clearness than they were before the early changes in these diseases had been described. By attempting to group all cases as examples of "appendicitis"—that is, an inflammation of the appendix—it is necessary for the teacher to qualify every statement, both in regard to pathological changes and clinical symptoms, in such a way that the subject is shrouded in difficulties and uncertainties, which make for hesitation and delay in diagnosis.

At the Annual Meeting of the Association in 1914 I brought forward clinical and experimental evidence in support of a plea for the recognition of two primary acute diseases of the appendix: (1) acute inflammation of its wall—appendicitis; and (2) acute obstruction of its lumen—a closed-loop intestinal obstruction.† These two diseases differ essentially in their pathology, their clinical symptoms, and, above all, in their danger to life. The profession, and particularly the teachers in the profession, have been slow to appreciate this fundamental distinction, which is, I consider, a primary requisite for correct and early diagnosis.

THE RESPONSIBILITY OF DIAGNOSIS

This falls mainly on the general practitioner, and for him it is all-important to have a clear picture of the early pathology of acute affections of the appendix.

Appendicitis

Inflammation of the wall of the appendix is of common occurrence, and may be the sequel to a blood-borne infection—as when it follows a tonsillitis—or to an intestinal catarrh. It is characterized by a turgid swelling of the wall of the appendix, frequently some ulceration of its lining mucosa, and, in some cases, by a plastic and occasionally suppurative local peritonitis. Clinically its onset is, relatively speaking, a gradual one, characterized by nausea, pain, and constitutional disturbances in the shape of fever, accelerated pulse rate, dirty tongue, and usually constipation, but occasionally diarrhoea. It is seldom a fatal disease unless complicated by an obstructive factor, by the sudden perforation of an ulcer due to a concretion, by a secondary intestinal obstruction, which is rare, or by an ill-timed operation.

Acute Appendicular Obstruction

This is a very fatal form of intestinal obstruction, because it is of the closed-loop variety which tends to early gangrene (Fig. 1). If we would but realize that

FIG. 1.—Obstructed appendix full of faecal matter; tension gangrene.

a sudden and complete obstruction of the lumen of an appendix, containing faecal matter, will, from the pressure of decomposing content, inevitably lead to tension gangrene within from six to twenty-four hours, and that gangrene will be followed by perforation, with the escape of stinking faecal content into the free and unprepared peritoneal cavity, we would regard the recognition of the onset of such an obstruction as one of the most important and responsible duties of a medical practitioner.

Is there, then, a clinical picture typical of this disease distinct and differing from that of appendicitis? Most assuredly there is. Here is the actual history of a case.

A boy, aged 14, who had previously enjoyed good health, except for occasional colicky pains in the abdomen, went to bed at night, apparently in his usual health. At 2 a.m. he awoke and cried out, complaining of severe colic, and vomited. He indicated to his mother that the pain was worst just above the umbilicus, but spread right across the abdomen. A hot cloth was applied to the abdomen, and in twenty minutes the pain had practically disappeared and the boy fell asleep. At 4.30 a.m. he was again wakened by a return of the severe colic, and again vomited. Heat was again applied, and the doctor was called. When seen at 7 a.m. by the doctor the boy volunteered that the pain had almost gone. *His pulse and temperature were normal,* but his face looked slightly drawn, and there was a slight rigidity of the right rectus muscle in its lower part, and a little tenderness.

The doctor advised a continuance of the hot applications, nothing but water by the mouth, and promised to return two hours later. At 8.30 a.m., and shortly before the doctor returned, the boy had another attack of colic and vomited. When examined at 9 a.m. he was again comfortable; his pulse and temperature were still normal, but his facial expression was slightly anxious, and the rigidity and tenderness in the right lower quadrant of the abdomen were still present, although not pronounced. Removal to hospital was recommended, and the boy was admitted with the doctor's card bearing the diagnosis "acute appendicular obstruction."

When seen in hospital at 10.30 a.m. his condition had not altered, except that his pulse rate was now 90; his temperature was still normal. The abdomen was opened at 11 a.m. A large appendix, tensely distended and stippled with greenish points of commencing gangrene, was carefully delivered through the wound and removed without bursting. The abdomen was closed without drainage. The proximal end of the appendix, for half an inch, appeared normal. Just beyond this, a concretion could be felt impacted. On opening the appendix about two drachms of stinking fluid faecal matter escaped from the part distal to the impacted concretion, and the mucosa of this part was dark green in colour and gangrenous.

* A British Medical Association Lecture (abridged) delivered to the Darlington Division on November 20th, 1930.

† I have since learned that Van Zwalenberg of Riverside, California, and Campbell of Belfast had come to similar conclusions.

In this case, owing to an intelligent appreciation of the pathology of the condition, the medical man hurried the boy to hospital and thereby saved his life. Had he temporized and waited for the constitutional signs of inflammation, the appendix would have burst, spilling fluid faecal matter into the free peritoneal cavity and determining a fatal peritonitis (Fig. 2).

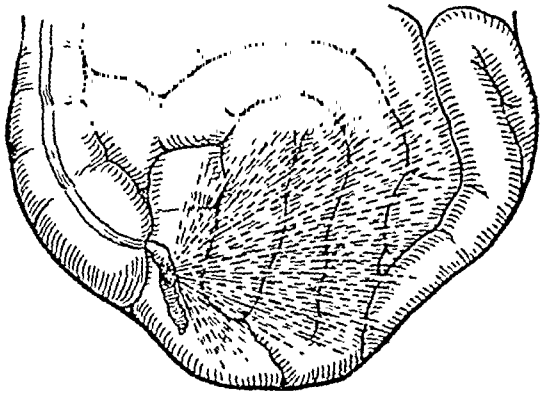

FIG. 2.—Rupture of obstructed appendix into the free peritoneal cavity.

Appendicitis is a misnomer for this condition; it is a form of intestinal obstruction, and gives rise to the signs and symptoms to be expected when a coil of bowel or a cul-de-sac, such as the appendix, containing faecal matter, becomes suddenly obstructed. The case cited above exemplifies the condition in its purest form. There are, however, cases in which, in the course of a true appendicitis, the obstructive factor supervenes and adds the new danger of tension within the lumen to inflammation of the wall. In such cases the obstructive factor may determine gangrene and perforation, but with less danger to life than in the primary obstruction, for the obvious reason that the primary inflammation has called forth a plastic peritonitis, and, when finally perforation does occur, it is into an area of the peritoneum more or less walled off by adhesions of omentum and intestinal coils.

If we analyse the mortality in the light of the pathology above described, we find that well over 90 per cent. of the deaths occur in the obstructed cases, usually designated as cases of "gangrenous perforated appendix." It is certainly true that in many cases the medical man is not called in until the gangrene and perforation have occurred, the trouble having been regarded as intestinal colic, and treated by what turned out to be nothing less than a lethal dose of castor oil. It is therefore necessary to teach the public the danger signals, and particularly the significance of recurring colic. But how can we expect the public to learn a lesson which is not yet taught in most medical schools?

In reading over the papers published during the past few years on the mortality from "acute appendicitis" I find no mention of appendicular obstruction or its significance, from either the pathological or the clinical standpoint.

THE RESPONSIBILITY OF THE OPERATING SURGEON

While the mortality in acute appendicular disease is attributable, for the most part, to delay in diagnosing and dealing with the obstructive type of case, the responsibility does not end with diagnosis. There are certain principles which should guide our operative practice in regard to:

1. When to operate and when not to operate.
2. How to avoid doing harm while doing good.
3. Management of complications.

When to Operate

All are agreed that when a diagnosis of acute disease of the appendix has been made within forty-eight hours of the onset of symptoms, immediate operation is advisable; in the obstructive case it is imperative. Where the diagnosis is made between the second and fourth days after onset, where signs of a spreading peritonitis are present, and where perforation has in all probability occurred, operation is surely indicated. Where the patient is seen four or five days after the onset, however, and has a palpable lump, but relatively little constitutional disturbance, immediate operation is unquestionably meddlesome. Nature has coped with the initial dangers, and resolution is proceeding quietly. If the surgeon blunders in, breaks down organizing adhesions and causes haemorrhage, obstructive intestinal complications not infrequently supervene, and a patient who was recovering falls a victim to ill-timed surgery. Honesty in reflection will bring to the minds of most surgeons cases of this order which they would willingly forget.

Those who state that there is no stage at which one should not operate may be skilful mechanicians; they are not surgical pathologists. Similarly, in the type of case seen seven or eight days after onset, where a diffuse peritonitis has occurred, and where the abdomen is distended and tympanitic but the pulse rate is slow, we can recognize a more or less successful reaction to a widespread peritoneal infection. The original focus now plays a minor part. In such cases there may be a large pelvic abscess which demands evacuation by as direct a route as can be found. Gross disturbance of intestinal coils, in order to discover the now buried and innocuous appendix, is surely not only meddlesome but entirely unwarranted.

In both the types of case just mentioned, conservative treatment, under careful observation, on the lines laid down by Ochsner, while tedious, is undoubtedly logical and sound in principle. McNeill Love and Hamilton Bailey in this country have recently emphasized these points. In America a greater discrimination and more thoughtful study of these cases have clarified the issue and confirmed the view that there is a time not to operate as well as a time when it is reprehensible to delay operation.

Minimizing the Harmful Effects of Operation

A certain degree of trauma and exposure of fresh surfaces to infection is inevitable in any operation for a deep-seated infective focus. A small incision is not the means by which to avoid trauma. The first criterion must ever be an adequate exposure of the appendix. This is especially important in the obstructive type of case where the distended and gangrenous organ may burst unless freed and brought to the surface in full vision of the operator. Even should twenty minutes be taken to free and deliver such an appendix unruptured, the time will have been well spent. Care, and not speed, is the essential in such cases.

Where a walled-off abscess is found in the right iliac region or pelvis, the appendix should be removed only if it is accessible without gross disturbance of adhesions. A patient will rarely die when an abscess has been drained; he may readily be precipitated into a dangerous condition if a determined operator feels it incumbent on him to remove the appendix regardless of Nature's barriers.

The peritoneum has a wonderful capacity for dealing with infection; not so the abdominal wall. For many years I was struck by the fact that after operations for a perforated appendix with peritonitis, where the peritoneum had been drained, the patients were seriously ill for several days, during which little or nothing came

from the drain. About the fourth or fifth day the general condition of the patients improved, and some foul discharge came away alongside, and not through, the drain; came, in fact, from the abdominal wall. In such cases the edges of the wound felt indurated and were tender, and, if stitches were taken out, foul sloughy material escaped. Anaerobic infection had been locked up in the abdominal wall, and had led to necrosis of fat, aponeurosis, and muscle. It was this that had accounted for the pronounced post-operative constitutional symptoms. Surely it must be that this added abdominal wall infection in some cases turns the scale between recovery and death.

Since adopting the plan of leaving the abdominal wound open, packing with gauze, in which is incorporated a small Carrel tube (Fig. 3), through which small quantities

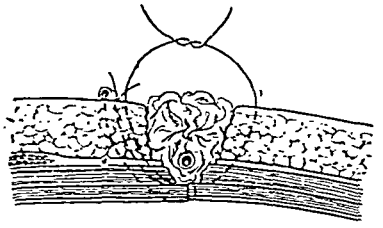

FIG. 3.—Open treatment of abdominal wound. Carrel tube seen on section in deeper layers of gauze packing.

of hydrogen peroxide are injected every few hours, I have found that sloughing is obviated, constitutional symptoms are absent, and healing is not delayed. Post-operative hernia is also less common, as no muscle or aponeurosis is lost by necrosis. The avoidance of all catgut sutures, and the use of the silkworm-gut looped suture for peritoneum and muscle, leaves no dead organic material in the wound as pabulum for bacteria (Fig. 4).

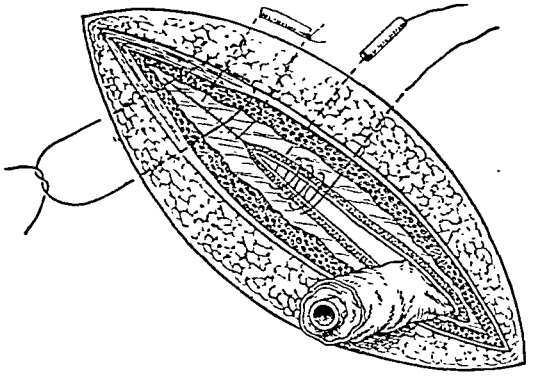

FIG. 4.—Method of using "looped sutures" of silkworm-gut in place of catgut for closure of deeper layers of wound.

In stout subjects the open treatment of the abdominal wound is especially necessary, as anaerobic infection is tolerated badly.

Post-operative Intestinal Obstruction

This accounts for a number of deaths in patients who have successfully dealt with the peritoneal infection. Where the obstruction is organic in nature and due to a binding down of lower ileal coils to the appendix bed, the patient will complain of some peristaltic pains associated with his distension and vomiting. In such cases, following gastric lavage, a tube enterostomy, or an ileo-colostomy, must be undertaken without delay, and the chloride loss from vomiting must be made good by subcutaneous saline infusions. Where, with distension, there is no clinical evidence of ineffective peristalsis, and paresis of the gut exists, continuous gastric drainage through a duodenal tube, the intravenous injection of 30 c.cm. of 5 per cent. sodium chloride solution, to replace loss of chlorides and stimulate peristaltic contraction, the application of heat to the abdomen, and the use of pituitrin, may excite peristalsis. Enterostomy has a limited value in this type, but permits of feeding and the replacement of loss of fluid and salt.

The Value of Caecostomy

In a strictly limited number of cases, where at operation a grossly distended caecum is found, a valvular tube caecostomy is unquestionably indicated. The comfort which this gives, the ready supply of fluid, and the absence of flatulent distension, make this a valuable addition to an appendix operation in selected cases.

CONCLUSIONS

1. The mortality from "appendicitis" remains as high as it was twenty years ago, because, while facilities for treatment have improved, diagnosis in the fatal type of case has not.

2. There is now very strong evidence that the fatal cases of acute appendicular disease are primarily cases of obstruction and not inflammation of the appendix. It is necessary to distinguish between these two types of acute disease, the clinical symptoms and essential pathology of which differ widely. The obstructive cases must be regarded and treated as belonging to the same category of urgency as internal strangulation of the intestine.

3. Free exposure at operation is essential in the obstructive cases.

4. While immediate operation is expedient in the early stages of appendicitis, delay is advisable in the resolving case, the danger of operation being greater than that of expectancy.

5. Where a large localized abscess is present, simple drainage with minimal disturbance is the safest line of treatment.

6. In cases with perforation and peritonitis, infection of the abdominal wound may be an important factor in determining a fatal issue. Open treatment of the wound is therefore advisable.

7. Post-operative obstruction accounts for a number of deaths. A timely enterostomy or ileo-colostomy may prove a life-saving measure.

THE FAMILIAL INFLUENCE IN GASTRIC FUNCTION

BY

FRANK L. APPERLY, M.A., M.D., D.Sc.

AND

JOAN H. NORRIS, M.Sc.

(From the Macleod Research Laboratory, Pathology Department, University of Melbourne)

In the course of some recent investigations into the question of heredity in gastric cancer we had occasion to examine, by means of the fractional test meal, the chemical and motor functions of the stomach in several members of each of a number of families. During this investigation we were struck by the frequency with which members of the same family gave closely similar results. This has been commented upon by several writers, notably Hurst,[1] who has on several occasions observed that duodenal ulcer with its accompanying "type" of stomach tends to run in families. The same has been noted with regard to achlorhydria and, to a less extent, "gastric diathesis." In 1923 one of us,[2] showed two instances of the close resemblance in the test-meal charts of parent and child. Since then we have collected two

more examples of the parent-and-child association, and, as shown in Group V, the similarity is seen in three out of these four cases.

Criteria of the Diathesis

In judging similarity of test-meal charts we have used three criteria—namely, emptying time (or where this is more than 1¾ hours, the volume of gastric contents recovered at that time), the shape of the curve, and the acidity. For purposes of classification we have divided these three criteria as follows:

1. *Emptying Time.*—(*a*) Rapid—stomach empty before 1½ hours; (*b*) normal; (*c*) delayed—more than 30 c.cm. found in the stomach at 1¾ hours.

2. *The Shape of the Curve.*—(*a*) Climbing or steadily rising; (*b*) flat; (*c*) falling—that is, a rise in the curve followed by a definite fall.

3. *Acidity.*—(*a*) Hyperchlorhydria (free acidity over 45); (*b*) normal; (*c*) hypochlorhydria (free acid present, but below 15); (*d*) achlorhydria.

In Table A are shown the gastric emptying times of healthy students, compiled—for comparison with the present series—from the combined figures of Bennett and Ryle,[3] Baird, Campbell, and Hern,[4] and Apperly and Semmens.[5] Our divisions of the acidity values are based on Bennett and Ryle's graphs of acidity curves of healthy students.[3]

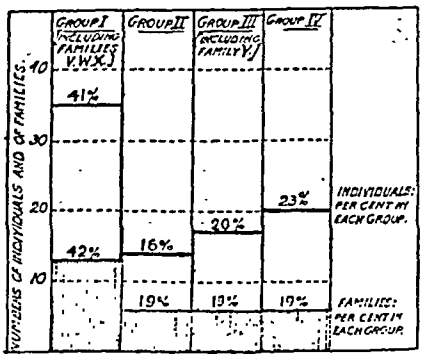
TABLE A.—*Rate of Emptying of the Gruel Meal*
(Figures given as percentages)

Observers	Average Emptying Time (Hours)	Stomach contains no Starch at (Hours)					
		0–1	1¼	1½	1¾	2	2+
Bennett and Ryle (100 men)	1.9	6	3	7	13	17	54
Baird, Campbell, and Hern (57 men) ...	2 1	5	7	14	9	17	48
Apperly and Semmens (53 men)	—	2	9	11	25	17	36
Above groups combined (210 men)	—	5	6	10	15	17	47

In the present series two or more members of 31 families comprising 86 individuals are examined and divided into four groups according to whether all members exhibit similarity in all three criteria, or only two or one, or in none. In the fifth group are four parents and their children.

In Group I (comprising 10 families—29 individuals) there is close resemblance in the three criteria in all members examined of each family. These similarities are more obvious when the figures are plotted together on the same chart. In Group II (6 families—14 individuals) there is complete resemblance in the test-meal charts of all members of each family in two of the three criteria, or the majority of members exhibit complete similarity. In Group III (5 families—15 individuals) these resemblances extend to only one of our criteria, and in Group IV (6 families—20 individuals) to none.

While it is difficult or impossible to express these results completely by a graph, that shown below will suffice.



It will be seen that nearly half the number of all individuals examined (41 per cent.) belonged to families all members of which showed a complete resemblance to each other as regards their test-meal charts in all three criteria.

GROUP I.—*Families in which the Test-meal Charts of all Members examined are Similar in All Three Criteria*

* According to the son, who is a medical man, the father died of pernicious anaemia, a condition invariably, or almost invariably, associated with achlorhydria.

† The father, a patient of one of us (F. L. A.), died of pernicious anaemia.

In some of the other groups, although this complete resemblance did not extend to all members, there were nevertheless pairs in a few of the larger families which were similar in all, or in nearly all, respects. Occasionally, where two distinct types appear in a family, possibly some resemble one parent and some the other. Although the above evidence strongly supports Hurst's contention that gastric types run in families (gastric diathesis) obviously the matter could be proved only by examining all members of several families over two or three generations while each member was still comparatively young and before gastritic or senile changes had occurred. Gastric function might prove to be hereditary in a Mendelian sense. To carry out such a set of observations would be almost impossible, owing to the difficulty of finding and persuading all members to undergo the tests, though until this is done we are hardly justified in using the term "familial" and in drawing other than tentative con-

clusions from our observations. A careful examination of our figures, however, would make it appear probable that such a relationship does exist.

Discussion

That gastric acidity, the form of the acidity curve, and the emptying time of the stomach should be similar in the various members of a family would not be surprising in view of previous observations. Apperly and Semmens[6 7] have shown that these characters depend largely on the tonus and activity of the gastric musculature and on certain chemical constituents of the blood. Further, the relationship of these characteristics to the ratio of pulmonary surface to body weight, and therefore ultimately to the build of the body and its constitution generally, lends further support to the hypothesis that they express family characteristics.

The marked resemblance in the test-meal charts in a large number of cases is, however, from another point of view rather unexpected. When we remember that in all instances the subjects were experiencing a test-meal experiment for the first time, with all grades of psychic disturbances consequential to the examination, the results seem to show that such influences count for much less than we have been taught to believe, unless we assume that all members of each family reacted psychically in the same manner. In actual fact this was not so, marked differences in psychic reaction being noted among the several members of the same family. It has indeed long been our view that temporary psychic disturbances have little appreciable effect on either the general form and magnitude of the acidity curve or on the emptying time of the stomach.

Conclusions

It has been asserted by various writers that the several varieties of normal gastric function are often inherited characteristics. We have investigated this question in a series of 31 families comprising 86 individuals, and our results support these statements.

THE INCISION FOR APPENDICECTOMY

BY

A. H. SOUTHAM, M.D., M.CH.OXON.
F.R.C.S.ENG.

HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY; LECTURER IN OPERATIVE SURGERY, MANCHESTER UNIVERSITY

Injury to a nerve is always an accident of some gravity, and injuries to the nerves of the abdominal wall are more common than is perhaps generally recognized. As a result of such injuries, atrophy of muscle is apt to follow, leading to some functional interference and incapacity.

The problem which is the best incision for the removal of the acutely inflamed appendix is constantly exercising the minds of surgeons. In a paper[1] published in 1924, in which an account was given of the after-results of the different types of abdominal incisions in general use, it was pointed out that a right inguinal hernia sometimes followed the McBurney muscle-splitting incision after operation in cases of acute appendicitis. Since that date several more cases showing this complication have been seen, enabling further observations to be made on this subject.

Incidence

It is difficult to give any accurate estimate of the frequency of the appearance of a right inguinal hernia following the use of the gridiron incision, as cases of this nature are seldom recorded, and it is doubtful if the connexion between the appendix operation and the subsequent appearance of the hernia is often recognized. The following figures are of some interest.

Roberts[2] states that the City of London Truss Society meets with twelve to twenty cases of this kind a year following the gridiron incision, and that he has never seen a hernia which occurred after the rectus incision. Griffiths[3] records ten examples in 100 consecutive cases of hernia, nine following the McBurney incision and one the Battle incision. In the latter case there was a large sac of the infantile type, the patient being probably predisposed to hernial formation. In describing the McBurney incision Romanis and Mitchiner[4] state that care must be taken not to damage the ilio-inguinal nerve, as this results in post-operative inguinal hernia—a complication seen in some 30 per cent. of cases. The hernia may appear at any time from a few months to a few years after operation; six months is about the usual period.

Etiology

In the paper already referred to it was pointed out that the hernia probably resulted from some injury inflicted on the ilio-inguinal nerve during the operation for the removal of the appendix.

It will be recalled that the ilio-inguinal and ilio-hypogastric nerves are branches of the lumbar plexus, and supply the muscles of the flank. The former runs forward on the iliacus and pierces the transversalis abdominis muscle near the anterior part of the iliac crest, and lies between the transversalis and internal oblique muscles. A short distance in front of the anterior superior iliac spine it passes through the internal oblique and then, descending in the inguinal canal, becomes superficial, after emerging through the external abdominal ring to supply the skin over Scarpa's triangle and the root of the penis. During its course the ilio-inguinal nerve gives muscular branches to the muscles below the anterior superior iliac spine. It is at the point where the nerve lies internal to the anterior superior iliac spine that it is liable to be damaged. This may take place when the muscle fibres of the internal oblique and transversalis are being split in making the incision, or the nerve may be included in the sutures when closing the wound, or, again, it may be involved in scar tissue at a later date, particularly in cases of abscess where drainage has been necessary. The nerve lesion results in paralysis of the muscles and the conjoined tendon round the internal abdominal ring and in the subsequent appearance of an inguinal hernia.

In three recent cases of right inguinal hernia following the muscle-splitting incision, where a second operation was undertaken for the radical cure of the hernia, the opportunity was taken to excise a portion of the ilio-inguinal nerve as it lay in the inguinal canal. On removal the three nerves were kindly examined by Professor J. S. B. Stopford, who reports as follows:

> All three nerves showed partial degeneration. The proportion of degenerate fibres varied in the three specimens; in two about half the fibres were affected, whilst in the other only about one-third. There was no evidence of interstitial changes, and the histological findings were consistent with those succeeding compression of a nerve by such things as scar tissue.

Comment

The choice of incision in a case of acute appendicitis merits the serious consideration of every surgeon. The view here taken is that in the McBurney muscle-splitting

incision the ilio-inguinal nerve is liable to injury, and is sometimes followed by the appearance of a post-operative right inguinal hernia.

The paramedian incision with outward displacement of the rectus muscle has the advantage that it can be safely extended to any length; this is undoubtedly the best incision for general exploration of the abdominal cavity where the diagnosis is in doubt and good access is required. In many cases, however, this incision will be found to be at some distance from the site of infection and will necessitate very careful packing off of the small intestine to avoid the risk of soiling the general peritoneal cavity when an abscess is present. For these reasons there is much to be said in favour of a lateral incision.

In typical cases of acute appendicitis localized to the right iliac fossa and in young patients, Battle's pararectal incision with inward displacement of the rectus muscle is regarded as being very satisfactory. This incision gives adequate exposure in such cases with the minimum disturbance of the inflamed parts; and as the nerves can be seen and readily avoided it rarely leads to any subsequent weakness of the abdominal wall. No case of inguinal hernia following the use of Battle's incision during a number of years has so far been encountered.

A METHOD OF BLOOD TRANSFUSION WITH SPECIAL REFERENCE TO CHILDREN

BY

DENIS BROWNE, F.R.C.S.

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

When a transfusion is given by an expert to an adult the best method is probably the direct transfer of unaltered blood,[1] [2] but this requires a sleight of hand that can only be acquired by constant practice, and a speed of flow that is dangerous to small recipients. Consequently, the indirect method described in this paper may be found useful both in transfusions given by the relatively inexpert, and in those given to children.

If I state the requirements of a satisfactory apparatus, it will be seen, without discussing other methods, why I have added a new one to their vast number. It should be capable of a very high pressure, but with complete control of every drop injected; it should be practically unbreakable and free from danger of spilling its contents. It should be easy to assemble, to transport, and to sterilize; and, most important of all, it should be workable by one man.

Physiological Dangers

Besides mechanical difficulties, however, there are physiological dangers in transfusion, and these should be outlined before the points of the technique can be assessed. The chief are:

1. Incompatibility of red cells and opposite serums—the most serious of all.[3] [4]

2. Incompatibility of white cells. A very interesting line of research, especially in regard to immunity.[5]

3. Sensitization of the recipient to the blood of a particular donor.[6]

4. Changes in the reactions of previously tested bloods. All these four dangers can be eliminated by direct cross matching, and by it alone.

5. Too large an injection. It is not easy to collect enough blood to harm an adult by overdosage, but it is very different with a child.[7] The safe limit is about 10 c.cm. to the pound, and if this seems small it should be remembered that for the average man it would mean two and a half pints.

6. Too rapid an injection. The circulatory system has a marvellous power of varying its capacity to suit circumstances, but it cannot do this instantaneously, and an amount of blood that would be harmless were its injection spread over twenty minutes, may produce death from distension of the heart if injected in five. As there is no reason to suppose that a baby makes the necessary adjustments more quickly than an adult, a full injection should take the same time in any case, irrespective of the actual amount given; so that a five-pound baby receives its 50 c.cm. drop by drop during twenty minutes at least. Apart from mechanical considerations it is possible that biochemical adjustments to the foreign blood may occur and need time for their consummation. The work of Cruchet,[8] even if we do not follow him to all his conclusions, is extraordinarily interesting in its suggestion that the rate of injection is the most important single factor in transfusion troubles. Finally, it is obvious that, should there be any incompatibility, the slower the injection the less the likelihood of getting in a dangerous dose before the signs of trouble declare themselves. The following notes on a child of 7 weeks illustrate this point:

August 8th, 1927: Admitted suffering from pyloric stenosis. Rammstedt's operation.

August 12th: After doing well, developed enteritis and became rapidly worse.

August 17th: Very collapsed and dehydrated. Blood transfusion by air pressure, and the whole dose of 60 c.cm. injected in about five minutes. Immediately afterwards the child died, the heart apparently stopping before the breathing. Post mortem, the heart was dilated and full of blood.

I have no doubt at all that in this case the cause of death was too rapid an inflow. Since then I have transfused many babies in just as weak a state, but I have made the injection far more slowly and have had no such trouble. I do not think that works on transfusion have given sufficient warning on this point. For instance, many advise a rate of transfer of 100 c.cm. a minute or more[9] without any caution against applying this speed to small children. When one considers that this might mean, in a 5 lb. baby, the equivalent of giving an adult three pints in thirty seconds, it seems reasonable to moderate it. Carlton, also,[10] when advocating Lindeman's[11] method, in which the blood is injected as fast as three workers can fill, empty, and clean syringes, advises that infants showing signs of cardiac distress should be put in a hot bath, while blood is withdrawn from the longitudinal sinus and adrenaline injected. Without pausing to discuss these restoratory measures, their mention does seem an admission that trouble in the very small is liable to occur.

7. Too cold an injection. A very common cause of reactions.[12] [13]

8. Products of digestion in the blood of the donor.[14]

9. Changes in the blood due to the time it remains outside the body.

10. Changes in the blood due to contact with foreign substances.[15]

11. Changes in the blood due to trauma to it.

12. Dried blood in the apparatus from previous use.

13. Unsuitable water in the citrate solution.[16]

14. Citrate poisoning. Many rather biased papers have been written both to prove that this occurs[17] and to prove that it does not.[18] My own opinion is that properly prepared citrate is quite harmless, and it should be remembered that before any one of the fourteen points given above can be proved responsible for a reaction, the other

thirteen must be definitely eliminated. Citrate has also been accused of spoiling the defensive powers of transfused blood,[19] and defended against this charge.[20 21] However, even if there should be a lessening of what is assumed to be the bactericidal power of the blood *in vitro*, it has yet to be proved that this persists *in vivo* after the citrate has been removed by the recipient's kidneys. In any case, it is clinically certain that citrated blood does transfer resistance to infection, whatever that may depend on.

15. Local damage to the recipient. Injection into the longitudinal sinus introduces an unnecessary risk of irremediable damage. I know of two cases of permanent damage to the Rolandic area caused by it. Injection into the peritoneal cavity can only be excused by the incapacity of the operator to put the blood into a vein.[22 23]

16. Injection of air into a vein.

17. Infection of either party to the transfer.[24 25]

I have purposely made the most of these dangers, but the list is more formidable in appearance than reality. To recognize most of the perils is to avoid them.

Testing the Bloods

A box fitted in the syringe case contains pipettes, test tubes, wooden sticks for stirring the blood, Hagedorn needles for pricking the skin, a white glazed tile on which to examine the bloods, a grease pencil for writing on it, a lens to magnify the reactions, a bottle of normal saline, and a bottle of spirit. The Moss grouping is a very useful indication of what the reactions of bloods are likely to be, but before every transfusion it should be determined what the reaction actually is. For this about 2 c.cm. of each blood is needed, and in many cases that of the recipient can be obtained from an operation wound, an injury, or a placenta. Two drops are picked up with a pipette and blown into 5 c.cm. of saline, and the rest is allowed to clot or is centrifuged in order to separate the serum. Then a drop of each serum is mixed with each opposite solution of corpuscles on a patch of the tile that has been isolated and labelled by the grease pencil, and the mixture watched for any clumping of the red cells. The dilution of the donor's blood makes the reactions easy to interpret by preventing rouleau formation, and if agglutination occurs it results in a very characteristic "cayenne pepper" appearance of red granules in the clear serum. If possible, twenty minutes should be allowed to elapse before it is decided that the bloods are compatible, but it is usually possible to make out the result in the first five minutes after they are mixed.

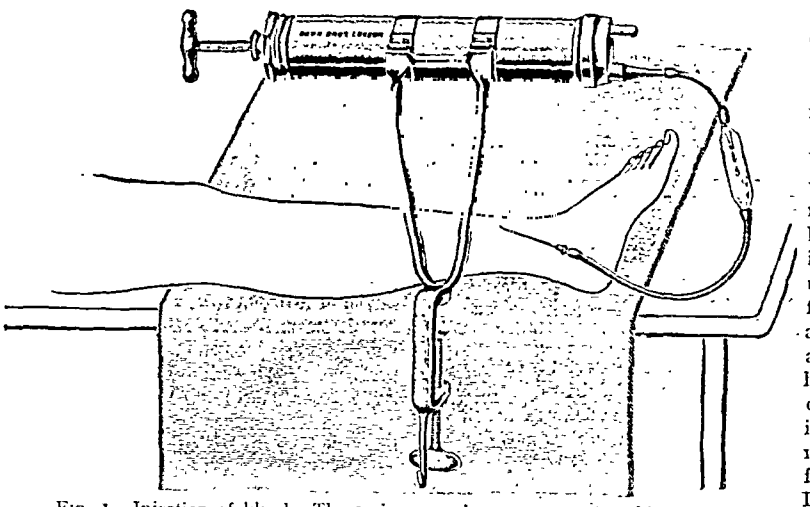

FIG. 1.—Injection of blood. The syringe can be on a separate table, or turned the other way.

TRANSFUSION

The apparatus consists of a metal syringe of a pint (600 c.cm.) capacity as described by Macintosh,[26] with the addition to the piston rod of a screw that can be thrown into or out of action by a small nut. When the syringe is full of incompressible fluid a slight forward turn of the screw will produce a very high pressure inside it, which can be changed to zero, and then to a negative pressure by equally slight turns the other way. When fluid alone is in the barrel it will only be driven out while the screw is actually being turned; but the whole character of the action is changed by the admission of air, which can become compressed and continue forcing out the contents while the piston is still. Consequently care must be taken to prevent this. On the side of the syringe are two lugs, by means of which it can be fixed to its stand (Fig. 1). This stand is an essential part of the apparatus, and clamps to any table in such a way that it will hold the syringe either horizontally for the delivery of blood or vertically for the collection of it, with a steadiness and safety beyond the powers of the most careful assistant. Instead of the glass nozzle of the original Macintosh model, which was extremely fragile and gave no indication of the flow of blood, there is a metal nozzle on the detachable forward end of the syringe, with a recess in its base in which a small piece of gauze can be packed if it is thought necessary to filter the blood, and to the end of this a Lauries's dropper, which acts as an air-lock and sight feed, is connected by two inches of rubber tubing. This tubing is of a special sort, with a smooth bore of 2½ mm., and walls almost as thick. Its small bore ensures that the flow of fluid through it is rapid, and so the risk of coagulation when drawing off the blood is lessened, while its thick walls minimize the loss of heat. Incidentally, it has the very useful quality of fitting the nozzle of a Record syringe, and though I have had the utmost difficulty in obtaining it, it is one of the most generally useful types of tubing I know. Another twelve inches of it lead from the Lauries's dropper to the introducing needle. This is either sharp, with a special short bevel for use when it is possible to thrust it into a vein through the skin, or carefully blunted at the end so as to be useful as a cannula when the vein has to be exposed. The ordinary intravenous cannula is far too large for a small child.

For withdrawing the blood I think the needle should have a "sclerectomy" point, with the walls bevelled inwards, and should certainly be no larger than size 14. It is connected to a foot of the special tubing, the other end of which is held by a small clip which screws on to the edge of the barrel of the syringe during withdrawal. The needle and tube should be rinsed through with citrate before use, and the flow of the blood through the small unchanging bore is so rapid that I have never had any trouble from clotting. The citrate is carried dry in sterilized ampoules of 2 grams each. One of these is broken into 100 c.cm. of *freshly* distilled water to give a 2 per cent. solution, 10 c.cm. of which is added to each 100 c.cm. of blood, and the remainder used for rinsing the tubes. If fresh distilled water cannot be got, boiled London tap water is perfectly satisfactory.

Withdrawal of the Blood

The stand is screwed on to a table over a sterile towel, as shown in Figure 4, and on to its hook the syringe (which has been thoroughly lubricated inside with liquid paraffin) is hung by whichever of its lugs leaves the top

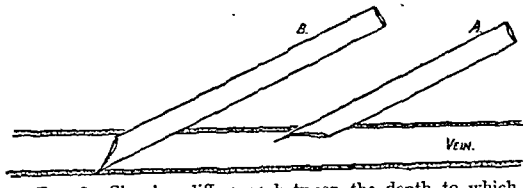

FIG. 2.—Showing difference between the depth to which the point must penetrate to get the entire orifice of the needle within the vein. A, with opening down, and B, with opening up.

in the most convenient position. Its piston is fixed at a position corresponding to the amount of blood required, and a suitable amount of citrate is poured into it. The usual cause of failure to tap the blood is the transfixion of both walls of the vein, and the best guard against this, as can be found by experimenting on a thin piece of tubing, is to put in the needle with the opening downwards (Fig. 2). If the opening is downwards it is also less liable to be blocked by the collapse of the vein's walls (Fig. 3). As the blood flows it is gently stirred into the citrate with the wooden rod supplied, and when enough has been collected the top is screwed on to the syringe, which is then removed from the hook. After all air has been driven out by screwing in the piston the injection tubing and needle is attached, and the syringe is set horizontally on the stand, where it is kept warm by covering it with cloths wrung out of hot water till it is needed.

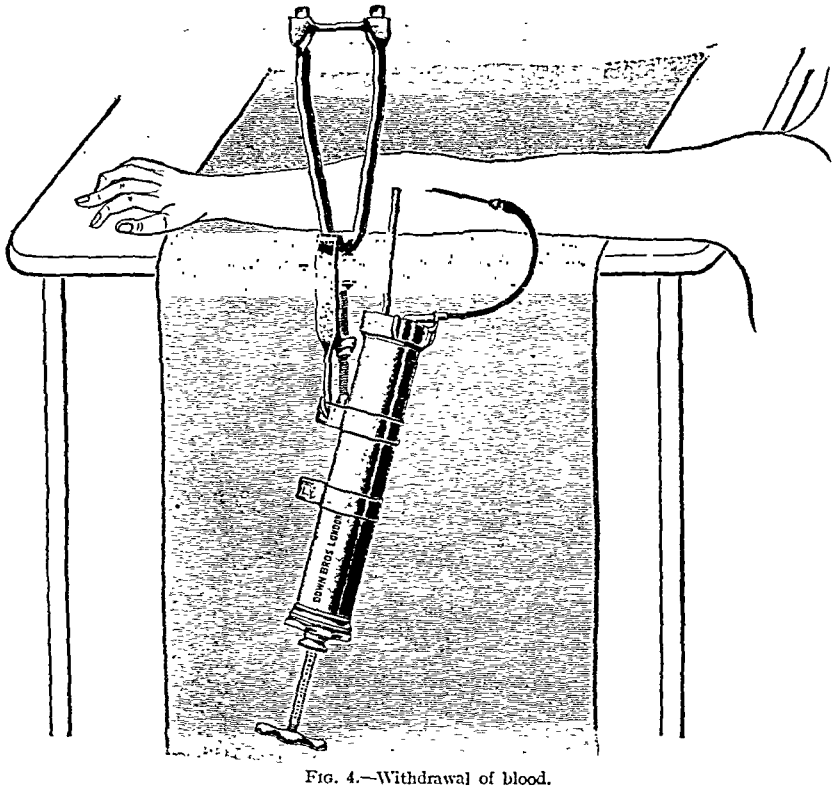

FIG. 4.—Withdrawal of blood.

Injection of the Blood

I agree with Robertson[27] that the best place for this is the internal saphenous vein where it crosses the lower end of the tibia. The patient cannot watch the operation, and the great veins through which the injection must pass

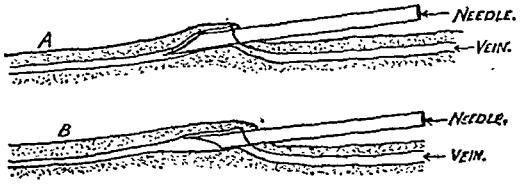

FIG. 3.—Showing way in which the collapse of the superficial wall of the vein occludes the opening if this is upwards (A), but not if it is downwards (B).

act as a safeguard against flooding the right auricle. If a vein is punctured through the skin a negative pressure should be kept in the syringe when the needle is buried, and then blood will rise in the air-lock as soon as tapped.

Indications

The range of these is becoming much more widely admitted, but a short review of them may be of interest, together with brief notes on a few of the more uncommon cases I have met with.

In spite of the universal admission that transfusion is the best treatment for haemorrhage and shock, many lives are still being lost and many recoveries made unnecessarily difficult for lack of it. Before any severe operation (including childbirth) it is a useful precaution to have a donor ready. Apart from the saving of time there is a saving in mental stress to all concerned if the possibility of a transfusion has been discussed beforehand. Again, in the Army a man's blood group might join his religion as a possibly useful piece of information on his identity disc. It is uncomfortable to many of us to think of those of our friends who might have been alive to-day had we had to-day's knowledge sixteen years ago; and for use in the field I do not know of any method which I would prefer to the one here described.

In the leukaemias, myelogenous and lymphatic, it can only delay the inevitable end; but this delay may be of great personal importance to the patient. In pernicious anaemia it may be of great use in strengthening the patient till he can take advantage of other treatment, while in haemophilia, though its aid is transient, it is the best remedy that can be given. Haemorrhage of the newly born may often be cured by the simpler method of injecting blood subcutaneously, but though this will end the bleeding it does not make good the loss already suffered. Transfusion does both, and should be used if the baby is in any danger of death. In acute secondary

anaemias[29] its results may be brilliant, as the following case will show:

D. R., female, aged 7, was quite healthy till ten days before admission, when she had what was apparently an acute tonsillitis with swelling of the cervical lymph glands. Her parents had noticed her to be very pale for three days. On admission she was very collapsed, and had a waxy pallor. The blood count showed red corpuscles 680,000 per c.mm., white corpuscles 33,000 per c.mm., polymorphs 75 per cent. A transfusion of 500 c.cm. was given. She made a steady recovery, was discharged fit three months later, and is now perfectly well, two years after the onset of the disease.

I am not sure that chronic infections do not provide the largest field for the use of transfusion. In low-grade septicaemias, empyemas, and similar conditions it may often make the difference between life and death, especially in children. However, it must be admitted that it is impossible to give absolute proof that the improvement seen after it would not have occurred without it.

In acute infections the general opinion seems against transfusion. I have had no experience of its action, and should welcome any information about it.

It often does very definite good in athrepsia and malnutrition of infants, as in the case given below.

G. G., male, aged 3 weeks. Admitted suffering from pyloric stenosis. Weight 5 lb., "big baby at birth," passing blood per rectum, and looking absolutely moribund. Transfusion 50 c.cm., Rammstedt's operation under local anaesthesia twelve hours later; uninterrupted recovery.

Transfusion seems the logical treatment for coal-gas poisoning, to replace the haemoglobin that has been put out of action by the CO, and in burns it helps both in the early shock and in the later toxaemia. Nephritis is usually given as a contraindication to it, but I have had two extremely interesting cases in which it seemed to avert certain death from uraemia. I give the histories without attempting to draw definite conclusions from them.

B. W., male, aged 10. September 6th: Admission, suffering from acute haemorrhagic nephritis. Blood and casts in urine, with large amount of albumin; blood urea 160 mg. to 100 c.cm. October 6th: Going downhill in spite of treatment; urinary output diminishing; vomiting; blood urea 250; transfusion 500 c.cm. October 10th: Much improved; passing more urine, with less blood and albumin in it; blood urea 140. October 31st: Blood urea 60. November 5th: Septic tonsils removed, as being probably the cause of the nephritis; "flare-up" of the nephritis, with blood urea rising to 120. January 1st, 1929: Sent out much improved; blood urea 40.

E. R., female, aged 7. May 2nd, 1927: Admission, suffering from acute haemorrhagic nephritis. Improved under treatment and was sent to country branch of hospital. August 9th: readmitted in uraemic coma; unconscious, dusky, and apparently dying; blood urea 122 mg. to 100 c.cm. Blood was withdrawn to the amount of 200 c.cm., and a transfusion of 500 c.cm. was performed. The effect was almost biblical, as she recovered consciousness on the operating table, and returned to the ward talking cheerfully. August 30th: blood urea 56. The patient was sent out much improved.

I have been able to find very little work on this subject,[28] and of course the action of the transfusion was not a simple dilution.

My thanks are due to the honorary staff of the Hospital for Sick Children, Great Ormond Street, for their encouragement in the work on which this paper is founded, and for permission to publish the cases described; and also to Dr. Aaron Signy for his advice and aid in the very important department of blood matching.

The instruments described have been made by Messrs. Down Bros., Ltd.

MECKEL'S DIVERTICULUM AS THE CAUSE OF ACUTE SYMPTOMS

BY

A. HARVARD BAKER, M.B., CH.B.

RESIDENT SURGICAL OFFICER, STOCKPORT INFIRMARY

During a series of 105 laparotomies, performed for various conditions during the three months June, July, and August, 1930, at the Stockport Infirmary, four cases were operated on by me which showed various forms of Meckel's diverticulum. In two of these, acute symptoms were caused, and in view of the comparative rarity of such cases some details may be of interest.

CASE I

A labourer, aged 52, was admitted at 11.55 p.m., on June 9th, with severe gnawing pain around the umbilicus. The onset had been sudden at 4 p.m. on the day of admission, but the man had remained at work for one and a half hours; since leaving it he had vomited three times. The bowels had moved at midday; they were usually regular. There was no pain in the back or shoulders, no urinary trouble, and no history of previous indigestion.

The patient was collapsed and covered with cold perspiration, his temperature being 97° F., and his pulse 80. The tongue was coated and dry. The abdomen was tender in the right hypochondrium and just below the umbilicus. Both recti were rigid. A rectal examination was negative.

An operation was performed at 1 a.m. on June 10th, a right rectus slide incision being made. Much free sanious fluid escaped, and coils of strangulated gut presented. On close inspection a Meckel's diverticulum, arising from the antemesenteric border of the gut, was found to be strangulated through a hole in the mesentery of another loop of gut. The portion of bowel bearing the diverticulum was tightly constricting a large loop of bowel, compressing its mesentery. This loop was drawn so tight that the strangulating bowel was only of the diameter of a pencil. The diverticulum was excised between clamps, but even then it was found impossible to reduce the strangulation until the constricting loop of bowel had been similarly divided. After reducing it the involved bowel was still blackened, and there was no sign of pulsation in its mesentery, into which considerable haemorrhagic effusion had taken place. Resection of three feet of intestine was therefore performed, with end-to-end anastomosis, and the abdomen was closed

with the introduction of a sheet-rubber drain of the abdominal wall. The diverticulum was about 3 inches in length, and had a clear opening of about 1/2 inch diameter into the intestinal lumen. It presented itself as a blackish oval cyst on the upper leaf of the mesentery. Its contents consisted of blood-stained fluid.

There was considerable vomiting for the first few days. Continuous rectal saline injections and two doses of anti-gas gangrene serum were given. The patient improved, and on June 16th was very comfortable; but two days later the wound broke down, with discharge of intestinal contents. Acute right parotitis developed on June 20th, and the patient went rapidly downhill, but lingered on till June 30th, when he died.

CASE II

A man, aged 30, was admitted at 11.30 p.m. on June 14th with severe pain in the pit of the stomach, which had come on suddenly at 8 a.m. just as he got out of bed; it was very severe and doubled him up, but it was intermittent. There was no vomiting, but some nausea, and no definite history of indigestion; there had been vague pains for a few weeks, which had been relieved by walking about.

His temperature was 100°, and the pulse 92. The tongue was slightly furred, and the abdomen rigid, tenderness being most marked in the epigastrium and the right and left hypochondrium.

An operation was performed on June 15th on the suspicion of perforated duodenal ulcer, the right rectus slide incision being employed. Clear fluid was present, and distended coils of small intestine presented in the wound. A Meckel's diverticulum 2½ inches in length and 1/2 inch in diameter was found, arising just below the antemesenteric border. The distal end was conical, and from the tip arose a fibrous cord about 3 inches long, the other end of which was attached near the root of the mesentery on the lower leaf. Over this cord a loop of bowel was kinked, the proximal part being slightly congested. The cord was divided between forceps, and the diverticulum was excised, the stump being invaginated by a purse-string suture since there was no tendency to stricture of the intestine. Appendicectomy was performed, and the wound was sutured in layers. Convalescence was uneventful, and he was discharged on June 29th.

CASE III

A man, aged 60, was admitted on August 14th at 12.15 a.m. There had been a sudden onset of severe abdominal pain the previous evening; it was situated at first low down on the left side, but spread over the abdomen. No vomiting had occurred, and the bowels had been opened the previous morning; there was no history of the passage of blood or mucus, nor of indigestion.

The patient was collapsed and sweating; the temperature was 98°, and the pulse 80. The tongue was clean. The abdomen was very rigid, especially in the upper half. There was no loss of the liver dullness.

The abdomen was opened, and a perforated gastric ulcer was discovered in the pyloric region of the stomach. There was some extravasation of stomach contents. The ulcer was sutured, and covered with a flap of omentum. Before closing the abdomen, a coil of intestine was noticed, bearing a Meckel's diverticulum, which was of almost the same diameter as the bowel, and about 1½ inches long. Its lumen was uniform and the end was not pointed or conical.

CASE IV

A married woman, aged 25, was admitted at midnight on August 15th. Pain had commenced about the middle of the previous day in the sides and the lower abdomen, and was colicky in nature. She had vomited twice on the morning of admission, and this temporarily relieved the pain. The bowels had not opened for two or three days. Micturition was normal, and menstruation regular; there had been some pain, but no intermenstrual discharge. The last period had ended one week before admission. There had been an attack of similar pain eleven years previously; the patient was ill for about six weeks, being relieved by enemata.

On admission, general tenderness and rigidity of the lower abdomen was present, especially in the right iliac fossa. The temperature was 100°, and the pulse 120; the tongue was moist and clean. Rectal examination revealed some faecal masses, and tenderness especially on the right side.

At operation, at 1 a.m. on August 16th, no causal lesion was found, but the caecum was large and ptosed, and the colon contained faecal masses. While examining the small intestine a relic of Meckel's diverticulum was found in its usual situation, about 2 feet proximal to the ileo-caecal valve. This showed as a bulbous dilatation of the intestine just distal to a slight constriction. There was, however, no distension above the constriction, and it was not thought that the lesion was causing any symptoms. Appendicectomy, therefore, was performed, but no operative treatment of the rudimentary diverticulum was undertaken. The patient made a satisfactory recovery.

I am indebted to Mr. J. T. Bailey, under whom the cases were admitted, for admission to publish details of Cases II, III, and IV, and to Mr. A. W. Berry for permission to publish Case I.

GONOCOCCAL RHINITIS IN AN INFANT

BY

HAMILTON KIRKLAND, M.B., CH.M.

ASSISTANT AURAL SURGEON, SYDNEY AND ST. VINCENT'S HOSPITALS

AND

ROBERT V. STORER, M.R.C.S., L.R.C.P.

SYDNEY, AUSTRALIA

We are reporting this case, first, because a perusal of the literature on gonococcal infections and diseases of the nose revealed practically no mention of the condition, and, secondly, on account of the interesting parental history, which resulted in its diagnosis.

A man, aged 42, consulted Dr. T. Spiers Kirkland in February, 1929, about deafness. A toxic focus was considered as the cause, and in view of a history of gonorrhoea the patient was referred to one of us (R. V. S.) for investigation. Examination revealed two hard sensitive nodules in the prostate. The prostatic fluid contained numerous pus cells. No gonococci were detected. Urethroscopic examination showed numerous infected Littré's follicles. The Neisserian infection reaction of the blood serum was negative. The urine was clear and contained no albumin, sugar, pus, or threads. A diagnosis was made of chronic prostatitis and Littritis, and appropriate treatment was instituted.

The patient had had gonorrhoea two years before marriage, but believed himself cured. He had been married eleven years, and had three healthy children, aged 10½, 9, and 6½ years respectively. There had been extramarital intercourse on one occasion only, four years ago, and on the following day a drop of yellow discharge had appeared. This disappeared without treatment. On no other occasion since marriage had there been any indication of uncured disease. His wife had an intermittent vaginal discharge which attracted notice after her first confinement.

While the husband was undergoing treatment for his prostatic condition his wife was confined, and soon after birth the infant developed a "cold," which did not react to the usual domestic treatment. As a matter of interest the husband was given two glass slides and asked to bring in smears of the nasal discharge for examination. Stained by the pyronin method, one smear showed numerous pus cells, staphylococci, and typical gonococci. The other smear was submitted to a pathologist, who reported as follows: "Numerous pus cells, Gram-positive cocci, and groups of Gram-negative diplococci, often intracellular and morphologically indistinguishable from gonococci, were present."

The baby, then aged 1 month, was seen (H. K.) on April 24th, 1929, with a history of unilateral (right) nasal discharge since birth. According to the mother this was most profuse in the early morning, and was yellowish in colour and sometimes blood-stained. The baby experienced difficulty in breathing while feeding, and was seized with fits of coughing at intervals. No discharge or foreign body was visible in the anterior nares. Conjunctivae were normal. The nasal mucous membrane was only slightly inflamed. On the next day a swab was obtained covered with thick yellow pus. A smear

was examined, and gonococci were found to be present. No Klebs-Loeffler bacilli were detected.

The condition was treated at first with mild antiseptic drops and subsequently with argyrol. At the end of a month the discharge had quite ceased.

COMMENT

This case presents many interesting features of clinical and sociological importance.

1. Gonococcal rhinitis may easily be overlooked as the true cause of a coryza. The bacteriological diagnosis is made difficult by the similarity of the *Micrococcus catarrhalis*, which is also Gram-negative and sometimes occurs in pairs, but is never intracellular.

2. The prophylactic instillation of drops into the baby's eyes at birth undoubtedly averted an attack of ophthalmia.

3. Inquiry into the history of the labour revealed a prolonged third stage, predisposing probably to the inoculation of the infant's nasal mucous membrane with infective vaginal secretion.

4. The diagnosis of gonococcal infection in married women presents many difficulties, but its possibility as the cause of a vaginal discharge should always be considered. When the infection is transmitted by a male with chronic gonorrhoea the urethra is seldom affected, and symptoms of mild endocervitis may alone develop. These may be attributed to a cervical laceration.

5. A thorough examination of the male genital tract before marriage is of paramount importance to exclude the possibility of latent disease.

6. The gonococcus retains its virulence for years in the glands of the prostate, seminal vesicles, and Littré's follicles, and a negative blood serum reaction does not exclude the possibility of a gonococcal focus. The best single routine test of cure is examination of the prostatic fluid for pus cells.*

The foregoing presents ample opportunity for criticism and discussion, and comment from our colleagues would be welcomed.

RUPTURE OF THE PANCREAS

BY

JAMES D. GRAY, M.D.Glas. AND JOHN C. HODGSON, M.D.Ed.

The rarity of this lesion encourages us to publish the following case.

The patient, a man aged 20, while playing football, was charged by another player and fell to the ground with his opponent on top of him. The latter's knee hit him on the abdomen. He attempted to carry on but failed.

He was seen by one of us within fifteen minutes of the accident, and presented the following typical picture of shock. He was pale and anxious, with beads of sweat on his brow, but he was quite conscious and intelligent. The lips and ears were pallid; the skin was cold and clammy, and of greyish hue. Pulse rate was 108 per minute and feeble; temperature was 97° F. Respirations were thoracic, sighing and irregular. He complained of severe abdominal pain, chiefly in the area under the umbilicus. The whole abdomen showed an absolute board-like rigidity, and his knees were drawn up to a marked degree.

He was treated by heat, and sent in to Ashford Hospital for operation with a provisional diagnosis of ruptured viscus. When seen in hospital by both of us an hour later his condition had considerably improved. Muscular rigidity was almost negligible, pulse rate 92 per minute and quite strong; temperature 97·6°; and respirations 20 per minute and regular. We decided to leave him under observation. Two hours later, however, his condition had changed. Pulse rate was still 92 per minute and strong, but he again looked haggard and anxious, and his abdomen showed muscular rigidity, most marked in the right hypochondrium. It was decided to operate at once.

A right paramedian incision was made, and the first thing evident was extensive fat necrosis, chiefly in the mesentery and omentum. Greenish-yellow areas were seen, varying in size from a pin-point to areas half an inch in diameter, these latter having an appearance not unlike gas gangrene. In addition, there was a large extravasation of blood under the peritoneal coat of the whole ascending colon and caecum. It was found impossible to stitch the pancreas, so drainage tubes were inserted and the abdomen closed. No wound was found in any other viscus.

The following morning the patient seemed somewhat better. His pulse rate was 96 per minute, temperature 98°, respirations variable. There was a copious greenish serous discharge from the drainage tubes. In the afternoon incessant vomiting of dark foul-smelling material set in, and he complained of tenesmus of the bladder. Twenty-four hours after the operation his heart began to fail, and he died forty hours after the accident.

Even during the operation his pulse was slow, and at no time till cardiac failure set in did it exceed 96 per minute.

Post-mortem examination revealed: (1) A tear of the pancreas anterior to the vertebral column; there the pancreas was changed into a dark haemorrhagic slough. (2) Extensive fat necrosis, especially in the omentum and mesentery. (3) A haematoma under the peritoneal coat of the ascending colon and caecum, but this was not so marked as during life. (4) Multiple adhesions of a fairly firm nature. (5) No free blood in the peritoneal cavity. (6) No tear of any other organ or of the gastro-hepatic omentum, and no bruise of the anterior abdominal wall.

REMARKS

The following points in this case seem noteworthy.

The Form of Violence.—This cannot be compared with that of most published cases—for example, a crush between the buffers of a train or a heavy fall of earth. The opponent's knee must have been applied directly over the vertebral column, when the muscles were quite lax, and the pancreas crushed across the backbone. It is strange that rupture of no other organ was found.

Muscular Rigidity.—Rigidity was present a quarter of an hour after the lesion and passed off only to recur. The textbook pancreatic lesion gives muscular rigidity as slight or absent. Is it possible that very early in the picture of a pancreatic lesion muscular rigidity does occur, and has already passed off when the patient comes under observation?

Pulse and Temperature.—The pulse was slow, and the temperature subnormal in this case. This is the rule in pancreatic lesions.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

AN UNUSUAL ABDOMINAL INJURY

Mr. C. H. Fagge, in his paper entitled "A plea for the earlier diagnosis of abdominal emergencies" (January 10th, p. 50), laid emphasis on the importance of the pulse rate in diagnosis. The following history of a case of abdominal injury may be of interest.

A man, aged 56, was admitted into the Stockport Infirmary in April, 1930, suffering from a penetrating wound of the abdomen. He had been transfixed by an iron bar about 4 feet in length and 1 inch in diameter. The bar entered the anterior abdominal wall 2 inches below the right costal margin and 2 inches from the middle line. It emerged behind, just above the crest of the right ilium at the outer border of the erector spinae muscle. The patient himself extracted the bar. On admission to the hospital he complained of pain at the site of the anterior wound. The pulse rate was 76, and the temperature 98° F., and there did not appear to be much shock. The tenderness was superficial, and the rigidity diminished with gentle local pressure, unlike the rigidity due to peritoneal irritation. There was no loss of

* The technique of this test is described in Storer's *Youth and Disease*, third edition, p. 122.

liver dullness, and no clinical evidence of a ruptured viscus. In spite of the fact that penetration of the peritoneal cavity must have taken place, it was decided to await symptoms, a half-hourly pulse record being charted. The local tenderness persisted for several days, but the pulse rate remained regular and normal. The only complication was an attack of bronchitis eleven days after the accident. X-ray examination eliminated the possibility of subphrenic abscess, and the condition soon subsided. The wounds healed quickly, and laparotomy did not turn out to be necessary.

In this case it was obvious that the peritoneal cavity had been traversed, and it seemed extraordinary that damage of a viscus had not been produced. The clinical sign of most value in determining treatment here was the condition of the pulse, the rate and tension of which remained normal until the temporary attack of bronchitis developed.

Manchester. D. M. SUTHERLAND, M.D., F.R.C.S.

CONGENITAL ABSENCE OF LEFT HALF OF DIAPHRAGM

Congenital absence of the left half of the diaphragm is a rare condition, and a report of the following case may be of interest.

A multipara gave birth to a full-time male child weighing 6½ lb. The labour was precipitate, and the baby was born before the arrival of a nurse. The mother stated that the child moved and made inspiratory efforts, but did not long survive after birth.

On post-mortem examination I found there was a complete absence of the left half of the diaphragm. The left side of the thorax was occupied by coils of small intestine, liver, and the left lung, which was quite unexpanded. The left parietal pleura and peritoneum formed an uninterrupted membrane. The heart was displaced to the right side, and the right lung was partially expanded. No other abnormality was found.

Congenital absence of the left half of the diaphragm is not incompatible with life. Cases have been recorded of individuals with this condition living to adult life. In one case recorded by LeWald[1] the patient was able to indulge in athletics, and was a successful entrant in a five-mile relay race.

Petersfield, Hants. TREVOR HOEY.

Reports of Societies

THE CHOICE OF AN ANAESTHETIC

At the meeting of the Medical Society of London on February 9th, with Dr. R. A. YOUNG, president, in the chair, the subject for discussion was the choice of an anaesthetic.

Dr. I. W. MAGILL, in opening, said that anaesthesia had done much to assist the progress of surgery, but for a long period it was enough for the surgeon if the patient was presented fully anaesthetized, and no inquiry was made as to method. Well-tried agents like chloroform and ether would produce good operative conditions, but their wholesale use was not always the best for the patient. Both were toxic, they did nothing to spare the patient the distressing anticipation of events prior to operation, induction was not pleasant, and recovery was attended by nausea and discomfort, so that the circumstances of the anaesthesia were often more dreaded than the operation itself. Turning to other anaesthetics, Mr. Magill said that nitrous oxide and oxygen anaesthesia was declared to be capable of producing abdominal relaxation, but unless the patient underwent a secondary saturation which amounted to a considerable degree of asphyxia, or was placed on preliminary medication to a more or less dangerous degree, this was not possible. Ethylene was more satisfactory, gave better relaxation, and could be used with as much as 20 or 30 per cent. of oxygen. He had found it particularly useful in thoracoplasty. The smell, however, was a disadvantage, and the risk of explosion also limited its use. It was in respect to the basal hypnotics that most progress had been made. Adequate basal hypnosis protected the patient from psychic shock, and diminished or eliminated post-operative nausea and vomiting. Of the various basal narcotics he found paraldehyde the most suitable for children. Of the derivatives of barbituric acid he had most experience of nembutal, though he would not wish it to be understood that he placed this above avertin in every case. With regard to spinal anaesthesia, much hostile criticism directed against stovaine should have been directed against faulty technique. At the Mayo Clinic spinal anaesthesia with novocain was the favourite method. The choice of anaesthetic must depend to some extent on the temperament of the patient. The general practitioner was frequently averse to the use of any new form of anaesthetic. The choice was largely dictated also by the nature of the operation. For abdominal sections he used spinal anaesthesia if the patient was able to stand a moderate fall of blood pressure. In exophthalmic goitre he gave an adequate basal hypnosis carefully gauged in accordance with the patient's condition, then local anaesthesia, with gas and oxygen held in reserve in case general anaesthesia was necessary. In operations on the nose performed under general anaesthesia, he believed the safest method to be intratracheal intubation; only by that means could an absolutely free airway be guaranteed.

Sir FRANCIS SHIPWAY spoke of the disadvantages of deep ether, especially the liability to bronchial complications. He believed that spinal anaesthesia should be more used in abdominal operations; it was safe, and the results after operation were extremely good. There were two or three drugs which afforded great satisfaction to the patient and to the surgeon. He did not want to draw any comparison between avertin and nembutal; he had not had enough experience of the latter to say much about it, but he believed that it had a great future. Whether it should be given by the mouth or intravenously was open to discussion. Avertin was always given by the mouth, and this he thought to be an extraordinarily valuable drug; he preferred it to paraldehyde—which he thought now rather out of date—for children. It was perfectly wonderful what could be done with this drug. Quite a number of children who had had operations for removal of tonsils or of the appendix were walking about to-day without ever knowing that they had undergone an operation. At a later stage in the discussion he said that he did not want to leave the impression that he thought basal hypnotics should be used as a routine.

Dr. C. F. HADFIELD thought that Sir Francis Shipway had spoken far too strongly of pulmonary complications following administration of ether. At the hospital at which the speaker worked, if there was any pulmonary complication he was sure to hear of it, and as far as he remembered during many years' experience, only one patient had died of a pulmonary complication after ether, and that was at a time when half the people in the ward had influenza, and the operating surgeon himself was affected. Dr. Featherstone in Birmingham some time ago analysed thousands of cases and found no

[1] LeWald, L. T.: *Arch. Surg.*, January, 1927, xiv, 322 (Part 2).

evidence whatever that there were more complications after ether than after other anaesthetics. The basal hypnotics were extremely useful, but a little erratic in their action. He recalled a patient who had undergone two operations for exophthalmic goitre with avertin; on the first occasion the avertin was very effective, on the second it seemed to have no effect at all.

Mr. C. HAMBLEN THOMAS said that in operations involving the upper air passages paraldehyde was easier than avertin. With paraldehyde the patient was in a sleepy, indolent condition; with avertin there was some struggling. Dr. GEOFFREY MARSHALL supported Sir Francis Shipway in his dislike of ether and chloroform; these were primitive methods of inducing unconsciousness. During the war he kept careful records of patients operated on for wounds of the abdomen, and certainly there was a large proportion of cases of serious bronchitis following open ether. He thought that in future patients would demand that they should be put to sleep in bed. But important as was the choice of the anaesthetic, he would add, speaking as one who was neither an anaesthetist nor a surgeon, that even more important was the choice of the anaesthetist. Dr. A. W. MATTHEW confessed that he was rather afraid of the basal hypnotics because of the question of idiosyncrasy, and of the fact that if these substances were got in they could not be got out. Their administration meant that a drastic poison was being given, to begin with, and on the top of this gas and oxygen or some other anaesthetic might have to be given. He believed that pre-anaesthetic terror was sometimes misunderstood. The real mental strain was not in facing the immediate prospect of an operation within a matter of hours, but in awaiting it over a long period of days or weeks. Sir JAMES DUNDAS-GRANT had found avertin serve excellently in an operation to remove cancerous growths from the larynx and to implant radon seeds, but he had discovered that there was a great disinclination to give this anaesthetic among those who had the choice. If avertin anaesthesia could be robbed of its dangers it would be one of the greatest blessings to surgery.

Mr. ARTHUR EDMUNDS, who confessed that he had done a whole afternoon's operations that day on patients who were under ether, said that he was very much in favour of gas and oxygen. It was not true to say that abdominal operations could not be properly carried out with gas and oxygen, together with perhaps a little ether to start with. He admitted that relaxation was not perfect; that was the drawback. He shared a little of the shyness which had been expressed regarding a dose of anaesthetic which had to be injected, but no doubt ultimately a reasonable method of using these drugs would be worked out. He was glad from the evidence of the present discussion to find that anaesthetists recognized the importance of the psychical or emotional aspect. Mr. ZACHARY COPE, speaking as one who himself had had chloroform and ether by the open mask, said that the experience was quite tolerable, and he did not have any unpleasant effects afterwards. The new drugs might have a great value provided they were judiciously used. Dr. Magill's method of putting the tube down the nose and larynx had resulted, in his experience, in perfect relaxation, and with that method the amount of anaesthetic needed was extremely small. He did not believe that the new anaesthetics would displace the older ones, as Sir Francis Shipway had suggested, but they would establish themselves in a limited field.

Dr. JENNER HOSKIN said that with intratracheal anaesthesia a free airway could be given and much less anaesthetic was needed. With regard to avertin, this was used extensively at his hospital for thyroid cases. One patient, not a serious case, did not come round after the anaesthetic. In the United States of America he understood that sacral anaesthesia was being used for prostate cases, and was supposed not to cause the amount of shock involved in spinal anaesthesia. Dr. FRANKIS T. EVANS said that pre-anaesthetic terror was a very real thing. Patients suffered during the induction period from the fear that they were going to be suffocated. If he ever had to have an anaesthetic he would be glad indeed to have avertin. Mr. H. B. BUTLER described certain cases of strangulated hernia, in which the strangulation had persisted for more than a week before operation. Some of the patients were quite pulseless, and in one case the operation was done without an anaesthetic being given. The patient recovered, and had been entirely insensible of what had taken place. In another case in which a large hernia was reduced the abdomen was infiltrated with novocain. Mr. C. HOPE CARLTON said that regional anaesthesia, as seen in Paris, was not very efficient. At one clinic there most of the patients whose operations he witnessed were only partially "under." At the Mayo Clinic, on the other hand, regional anaesthesia was successfully practised for prostatic cases, and was also found to have great value in vaginal hysterectomy and in incisions of the rectum. In hernias it was also used, but, he thought, without much success. It was well to remember, before giving a wide application to the Mayo experience, that the bulk of the patients at that clinic were of the Nordic or Swedish type, had lived an open-air life, and were very healthy and tolerant of pain. He did not know whether the same procedure would have similar results with the Latin type.

Sir WILLIAM WILLCOX, speaking of basal anaesthesia from the toxicological point of view, said that the disadvantage of the basal anaesthetics was their toxic properties. Luminal was one of the most poisonous of the barbituric group; he had seen a number of fatal cases of poisoning with it. Nembutal was one of the quickly acting barbituric acid compounds, the effect of which was more transient than in the case of most of them, but he urged the necessity of great caution in its use and great care in its dosage. If a broncho-pneumonia supervened upon the administration of this anaesthetic, no treatment for it was of any avail. There was a good deal of idiosyncrasy with regard to these drugs. The useful dose would be one which produced a blunting of the sensibilities rather than coma. If coma were produced with nembutal the danger zone was reached. Avertin was a narcotic, like chloroform or ether, but rather more toxic than these, and it was necessary here also to be careful, because one might have patients who, after what was apparently a normal dose as calculated by the individual weight, went into a deep coma lasting many hours and causing great anxiety. With regard to Dr. Hadfield's point about the erratic action of avertin, it was probable that during the interval between the two operations the liver had regenerated, and the regenerated liver was more resistant to avertin on the second occasion.

Dr. PARRY PRICE spoke of 350 avertin administrations without any death, although there had been one or two rather serious cases of collapse. Avertin was especially useful in ophthalmic surgery. With regard to pulmonary complications after anaesthetics, he often wondered whether these did not arise more from mouth sepsis than from ether. Mr. J. L. JOYCE spoke on co-operation between the surgeon and the anaesthetist, and also mentioned one case which had had five administrations of avertin, and every time the anaesthesia appeared to be deeper and the sleep longer.

Dr. MAGILL, in response to a request by the PRESIDENT to say something about the choice of an anaesthetic in regard to the organ or system primarily involved, said

that in the surgery of the brain and spinal cord he employed intratracheal nitrous oxide and oxygen with a minimal amount of ether; as the operation proceeded the ether could be cut out. For operations involving the chest in the tuberculous subject, if the duration was short, as in the resection of one or two ribs, it could be done under local anaesthesia, but for the big operations he preferred ethylene, and for abdominal work spinal anaesthesia.

THE INTRAVENOUS USE OF GERMICIDES

A special discussion on the indications for, and the intravenous use of, germicides took place at a combined meeting of the Sections of Surgery and Pathology of the Royal Society of Medicine on February 4th. Mr. C. H. FAGGE, president of the Section of Surgery, occupied the chair.

Mr. V. ZACHARY COPE began by defining a germ as any pathological micro-organism, whether protozoal or bacterial, and a germicide as any substance of known and fixed chemical composition which would kill germs either directly by contact with them or indirectly by unfavourably affecting their environment in the body. The indications for the intravenous use of germicides depended upon their proved or presumed value. In the case of widespread infections the intravenous route was ideal, provided that the drug was efficacious; and had no serious deleterious action on the body. In all cases the efficacy of the drug must finally be judged on clinical evidence. Intravenous therapy had been more successful with the protozoa than with the bacteria. The effects of compounds of arsenic upon the spirochaetes of syphilis, framboesia, and relapsing fever, of antimonial compounds on the Leishman-Donovan body, or emetine hydrochloride on the *Entamoeba histolytica*, and of quinine on the malarial parasite, were sufficiently striking. Bacterial diseases did not so readily respond to the intravenous injection of germicides. Clinical evidence supported the intravenous injection of salvarsan in cases of anthrax, but rejected the use of optochin in pneumococcal pneumonia. Sanocrysin appeared to have an indirect effect on some cases of tuberculosis. Some compounds of chaulmoogric and hydnocarpic acids had proved their worth in leprosy. A reliable drug for intravenous use in the treatment of severe septic infection had not yet been found. Most antiseptics appeared to be harmful when injected into the veins. Mercurochrome had been strongly recommended, but opinion as to its value was variable. The work of Professor Fleming had proved that whatever beneficial effect these germicides had must be indirect. Speaking as a clinician, Mr. Cope said that he often felt the force of the criticisms made against clinicians by those who said that they too readily adopted methods of treatment based upon insecure scientific foundations. Both surgeons and physicians were too ready to try a remedy because it was new rather than because it had good credentials, and to believe that the presumed remedy had cured when cure was the result.

Professor ALEXANDER FLEMING defined a germicide as a substance which entered into destructive combination with a microbe. It was not legitimate to claim as germicides substances which *per se* did not kill microbes, but which when injected intravenously were reputed to undergo or produce some mysterious change by which the bacteria were destroyed. A germicide could only be effective in destroying microbes in the blood stream if it was possible with safety to obtain in the circulating blood a concentration of the chemical lethal to the microbes, and to maintain such a concentration sufficiently long for the microbes to be destroyed. There were tests by which it was possible to ascertain with a considerable degree of accuracy the bactericidal power of blood or serum, and by such tests it could be shown whether or not a chemical injected would enhance such power. It was obvious that any germicide injected intravenously would be at its maximum concentration in the blood immediately after the injection, and before it had had time to be removed from the circulation. It followed, therefore, that the maximum germicidal effect should be manifest in the first few minutes after the injection. Many germicides which had been recommended for intravenous injection had been tested, but almost all had failed to fulfil the two requirements he had just instanced. With most germicides the amounts recommended for intravenous injection did not, when diluted in the blood, give a concentration which was lethal to microbes. In some cases sufficient germicide could be injected to produce a lethal concentration, but the chemical disappeared from the blood with such rapidity that it was impossible that it could have had any bactericidal effect. Professor Fleming proceeded to show a number of diagrams to illustrate the failure of various drugs. He showed that with sanocrysin in the dilution of 1 in 2,500 in human blood, tubercle grew just as well as when none of the substance was present. Flavine killed the ordinary pyogenic microbe, but the effect on the leucocytes was just about ten times as great. The only hopeful example in Professor Fleming's series was novarsenobillon in the presence of *Strep. haemolyticus*. He added that he did not wish to be entirely destructive, and he referred to the undoubted bactericidal power, as tested on rabbit's blood, of common salt.

Mr. P. H. MITCHINER did not believe that a germicidal action could be obtained from any chemical in the blood. When it was considered that chemical antiseptics injected intravenously had to be given in such strength as to have an optimum lethal action on the micro-organism, and yet not to impair the defensive action of the leucocytes or other tissue cells, it must be admitted that they could not hope to get any direct germicidal action by the intravenous injection of such substances. He was fairly certain that in the majority of instances the intravenous injection of germicides, so-called, was more harmful than beneficial to the patients in cases of septicaemia. No criterion was available in any individual case as to the dosage of germicide which was likely to produce the most beneficial result, and he would even go so far as to say that in the same patient at different stages of the septicaemic infection different doses were necessary to produce an optimum result. Test-tube experiments were of no value at all in estimating the action of bactericides on micro-organisms in the human body. A dose lethal to a micro-organism in a test tube might permit that organism to grow very much better in the blood than if no antiseptic had been added. He mentioned the work of some of his colleagues in other departments of St. Thomas's. Colonel Harrison, in the venereal diseases department, had told him that the intravenous injection of arsenical compounds in syphilis produced the definite disappearance of the spirochaete, but he did not claim a direct germicidal action, and it appeared that it was customary to have all patients who had been treated with a full course of neosalvarsan back in a year's time, when a large proportion of the cases showed a positive Wassermann reaction. In the tuberculosis department, on the basis of an experiment with twenty cases treated with sanocrysin, the results were reported absolutely negative. With regard to septicaemias, he felt strongly that in some cases the substance injected had nothing whatever to do with the recovery of the patient. He attributed the results to increased germicidal power of the body tissues due to protein shock. The injection of the substance, if it did any good at all, did it by altering the balance of resistance in the body tissues by some means about which he knew nothing. The clinical

indications for the injection of these so-called germicides were: (1) failure of the patient to react to general antiseptic treatment, and (2) absence of leucocytosis in the blood count.

Mr. T. H. C. BENIANS said that for practical purposes the discussion might be limited to the treatment of streptococcic and staphylococcic septicaemias. When organisms were in the body they had, dead or alive, to be assimilated by natural processes, and this raised the question how far it was worth while taking liberties with body cells, remembering that body cells were in the main far more permeable than bacteria. At one end of the scale was the acute toxic infection with no pyogenic reaction; at the other a slow pyaemia with marked thrombosis, embolism, and pus formation. The organisms in the first type were usually not multiplying freely; they were fragile, and subject to lysis by the blood and tissues: the picture was one of acute toxaemia. Some form of antitoxic treatment rather than disinfection was needed. In the second type the patient did not die from bacterial toxins, but of the vigorous pyogenic reaction. Here the difficulty was to get at the bacteria on account of the mechanical conditions, and some control over this excessive reaction was indicated. It was in the various grades of infection and reaction that lay between these extremes that germicidal treatment might be of avail, and where it might be worth while balancing the question of injury to the bacteria with that of injury to the phagocytic tissues.

Dr. L. P. GARROD related particulars of some experiments to determine in what concentration certain drugs would kill or inhibit *Strep. pyogenes* in the presence of blood. Eusol had no action whatever. Acriflavine had a much greater inhibitory than bactericidal effect. Mercurochrome had no bactericidal action in the concentrations employed, though at 1 in 100 it had a small degree of inhibitory action. He believed that the reason why mercurochrome was looked upon as so effective was because the discoverers of the drug—Young, White, and Swartz—made their experiments on urine, which gave an erroneous idea as to its efficacy in killing *Staph. aureus*. Mercurochrome was a very weak germicide indeed.

Dr. G. M. FINDLAY said that the more differentiated the parasite the more easily was it got rid of in the body. Protozoal diseases were fairly easily eradicated, but bacterial diseases were almost unaffected by chemotherapeutic agents, and ultra-microscopic viruses were entirely unaffected. He discussed the possibility of association between the chemotherapeutic drug and immune bodies. Dr. BOUSFIELD pointed out that a more efficient type of serum was now available than was the case five years ago, and he thought that against the rather pessimistic note struck in that discussion, the fact that the destruction of *Strep. haemolyticus* could now be approached with some success ought to be placed on record. Dr. JULIUS BURNFORD said that Dr. Benians had put forward a very broad-minded view that much of the work on germicidal agents ought not to be relegated to the laboratory worker. It was forgotten that many of the results obtained in medicine, even in its present scientific state, were entirely empirical, and he confessed himself disappointed that the discussion had not elicited more of the experience of clinicians, empirical though it might be. While a certain amount of scepticism was perhaps necessary, repeated treatments with a drug that was at least harmless to the patient furnished the hope that a germicide might be found which would do much good in certain infections.

Professor FLEMING, in a brief reply, expressed the view that clinical experiment in estimating the value of a germicide was useless, while Mr. ZACHARY COPE contested this view, and also refused to accept the opinion that the only way whereby an agent could kill a microbe was by combining with it. He believed that the search for an indirect effect or reaction brought about by the germicide was a very hopeful line to take, and that future investigation would show that drugs could kill bacteria, not only by combining with them, but in other ways.

EUROPEAN WOMEN AND CHILDREN IN THE TROPICS

At a combined meeting of the Sections of Tropical Diseases and for the Study of Disease in Children, on February 5th, with Dr. GORDON THOMSON in the chair, the subject for discussion was "The adaptation of European women and children to tropical climates."

Dr. A. R. NELIGAN pointed out that the European in the Tropics might need to adapt himself to the conditions for a very long period, if not for life, and to that end family life was an important factor, especially in preventing or diminishing home-sickness. An equable temperament and a natural adaptability, such as Scots possessed in a high degree, also went a long way. Young children in the Tropics required more sleep than in Europe, and their lives should be kept as free from excitement as possible. It was important to have a European nurse, who, however, should be carefully tested before going out. Many of the complaints made with regard to the Tropics arose, not so much from climatic difficulties, as from altered social and sanitary conditions. In children living in the Tropics the heat-regulating centre was easily disturbed; they grew rapidly, weight was usually below the European level, and there was also a rapid development of intelligence, tending to precocity.

Dr. ALDO CASTELLANI, K.C.M.G. (Hon.), said that the climate of the lowlands of the Tropics was not very suitable for the majority of Europeans; they were not as healthy there as in their accustomed environment. An exceptional few, however, were better in the Tropics than in Europe. The effects of tropical climate were definitely more marked in women than in men, especially in relation to the nervous system. The average European woman in the Tropics looked debilitated and pale, and was more "nervy" than the average man; she needed more frequent changes to the hills, or to Europe. The incidence of serious disease, however, was less among women, probably because the greater range of movement of men exposed them more to bacterial and protozoal infections. Babies up to 18 months, or even more, stood the hot climate well, but after 10 years of age children—boys especially—did less well; usually they were sexually precocious. Children should be sent home at not a later age than 10, and their return to the hot climate should be postponed until they were at least 20. Very few European women in the Tropics could nurse their babies for more than a few weeks. The climacteric, also, was more trying for European women there, and neurasthenia more likely to result.

Dr. H. S. STANNUS said that the advent of European women in the Tropics was a potent factor in raising the general standard of health in the community in which they were placed, thanks to the enlightened domestic and social regime they instituted. He proceeded to discuss the meteorological and other factors in which the Tropics chiefly differed from more temperate climes, and also touched on the effects of glare, ultra-violet radiation, and the causes and effects of pigmentation. Dr. G. W. BRAY thought that it was at present beyond the power of the European to adapt himself to tropical climates if that implied the wholesale immigration of white men and women, their maintenance in the same state of physical vitality, their retention of ordinary mental and moral

standards, and their ability to reproduce and transmit like characteristics to the next generation. With all the hygienic advances which had been made, little progress could be reported with regard to the neurasthenic complex, which still figured highly in the statistics in respect to officials invalided home. A psychological drawback was not only the loneliness in comparison with home conditions, but the proximity to races having an inferior outlook and standard of living. For the preservation of their health European women should engage in healthy pursuits, and return to the homeland at regular intervals. More careful housing and dieting should be aimed at, less club life, and less alcohol, and to these ends the influence of an intelligent wife was very helpful.

Dr. Hugh Thursfield thought that the factors mentioned in regard to the social aspect of the Tropics were also true of some temperate regions—as, for example, the Western portions of Canada—except that there the Europeans were not in proximity to a subservient race. Mr. A. F. MacCallan spoke from his experience of Egypt, especially on the effect on the eyes of summer glare. He also said that it was necessary to forbid native maids and nurses to touch European children because of the great risk of infection with trachoma. Dr. J. B. Christopherson pointed out that many of the disabilities of the Tropics, especially in the matter of dress and hygiene, had been minimized or overcome by missionary women. It was important that women should have something to occupy them, mentally and physically. Dr. K. Edmundson spoke of the trying conditions in those parts of the Tropics where six months of dry heat was followed by the same period of moist heat. Women and children could not live for more than a year continuously in such climates. Dr. S. T. Theobald said that the white woman in the Tropics was apt to suffer from late nights, ennui, and excessive alcohol. Some people could live and enjoy good health in any part of the Tropics.

PAIN IN THE LOWER ABDOMEN

At a meeting of the Manchester Medical Society, held on January 14th, with the president, Mr. Howson-Ray, in the chair, Dr. W. Fletcher Shaw read a paper on lower abdominal pain. He pointed out that this common symptom in women might be produced by a number of different conditions—medical, surgical, or gynaecological—and it was therefore necessary to keep all these in mind when investigating a case. Unless a diagnosis was made and the true cause of pain discovered patients might be subjected to a useless operation. He pointed out that the gynaecological conditions which most commonly produced this chronic aching pain were lax pelvic floor and pelvic adhesions; other conditions were fibroids, ovarian cysts, carcinoma cervicis, chronic cervicitis, malignant ovaries, endometriomata, prolapsed ovary, retroflexion of uterus, endocrine irregularity, chronic endometritis, subinvolution, varicocele, polypi, and carcinoma of the body of uteri. Many patients were mothers of young families, and were worn out mentally and physically with their responsibilities; this was often much more important than a minor pathological lesion, and in such cases a complete rest and holiday away from the family did more good than an operation.

Dr. Frank E. Tylecote remarked on certain conditions causing lower abdominal pain which did not, at first at any rate, require the surgeon. He mentioned such lesser maladies as constipation, haemorrhoids, abdominal fibrositis, and pain from adenitis caused by superficial irritation from a focus of sepsis in the leg, and stated that he found it worth while to inspect the lower limbs in doubtful cases of lower abdominal pain. Statements made by patients that they were not constipated should not be accepted without confirmation, and in cases of diarrhoea the existence of loose stools due to irritation by a scybalous mass should be remembered. Constipation and haemorrhoids were common causes of abdominal pain, while an overloaded colon might give much discomfort, pain, toxaemia, and occasionally considerable pyrexia. In cases of suspected malignant disease of the descending colon or rectum a single rectal examination or a single barium enema might fail to disclose the condition, and sigmoidoscopy might not show a growth which was present. If a doubt persisted, the examinations should be done again. Endothelioma of the peritoneum was a condition which might cause very severe lower abdominal pain at a time when physical signs might still be very indefinite, but ascites would soon follow. Enteroptosis was a common cause of the symptom under discussion, but the appearance of the abdomen in the erect posture would often suggest the diagnosis, while visceroptotic pain had well-recognized characteristics. Abdominal influenza might begin with diarrhoea without vomiting, but with collapse, although it was oftener thought of as a diagnosis when both vomiting and diarrhoea were present. He mentioned a case of a youth in whom there was much melaena, great collapse, and a typical influenza tongue and throat; improvement did not begin until large doses of salicylates were given. Intestinal crises associated with Henoch's purpura, with angioneurotic oedema, with tabes dorsalis—the so-called "enterospasm"—and even with minute embolic formations in the course of a case of septic endocarditis, should never be forgotten. Abdominal Hodgkin's disease in its early stages was most likely to be confused with other causes of abdominal pain, but in its later stages abdominal pain might occur from deposits in the vertebrae. Abdominal herpes zoster might be preceded as well as followed by most intense abdominal pain. The best early guide to the diagnosis was the well-localized distribution of the pain. In the consideration of lower abdominal pain typhoid fever should not be forgotten, and the watch for perforation was always an anxious feature of this disease. Entire loss of abdominal movement was the best sign, but complaint of pain on micturition he had known more than once to be the first indication of this complication.

Mr. Philip R. Wrigley pointed out that pain in the lower abdomen might be due to an extra-abdominal lesion affecting the eleventh and twelfth dorsal and first lumbar nerves in any part of their course, and instanced a case of perinephritis, in which for a considerable time the dominating symptoms were pain in the right iliac fossa and agonizing pain in front of the knee. He suggested that the character of the pain, whether it radiated, remained localized, or partook of the nature of renal, biliary, or intestinal colic, was often of value in determining its cause. He discussed the relation of pain to food, and to function of bowels and urinary tract, and mentioned the differential diagnosis between appendicular lesions, renal and ureteric calculi, tuberculosis of the mesenteric glands, and some other lesions. He uttered a warning against appendicectomy without careful investigation, and emphasized the fact that the cause of pain in the right iliac fossa was often to be found in the left iliac fossa, this being due to distension of caecum secondary to obstruction in the sigmoid colon from carcinoma or diverticulitis. He was not quite convinced that visceroptosis *per se* was a cause of abdominal pain; he believed that the pain felt by these patients was due to some associated condition such as infection or constipation, or to some independent affection, quoting cases in support of his view.

LARYNGOLOGY

A meeting of the Section of Laryngology and Otology of the Royal Academy of Medicine in Ireland was held on January 16th, with the president, Sir ROBERT WOODS, in the chair.

Dr. T. G. WILSON showed a case of bilateral abductor paralysis of the vocal cords. For eighteen months the patient had had a carcinomatous growth of the laryngo-pharynx, which had been treated by deep *x* rays with, at first, a considerable degree of success. Three months ago he had suddenly developed bilateral abductor paralysis for which immediate tracheotomy was performed. Dr. Wilson showed water-colours on the epidiascope illustrating the case at various stages. Dr. KEOGH said that it was easy to see how toxic influences could affect the nerve centre for the abductor muscles in the floor of the fourth ventricle, and how one bundle of fibres in the recurrent nerve could be influenced by pressure. He pointed out the parallel between the abductor muscles and flexor muscles generally.

Dr. PATRICK DEMPSEY showed a case of laryngo-fissure for epithelioma of the vocal cord. The patient, a female aged 73, complained of hoarseness, which had existed for three months. Laryngological examination showed that the middle third of the right vocal cord was occupied by a pale warty-looking growth. The appearance was typical of epithelioma, and a portion removed by the direct method for microscopical examination was pronounced to be squamous-celled carcinoma. Laryngo-fissure was performed a few days later, a portion of the right arytenoid being removed in the effort to get well behind the growth. There was very little haemorrhage during the operation, but one hour afterwards blood was freely coughed up both from the mouth and through the tracheotomy tube, which had been left in position. Dyspnoea was urgent, and the entire wound had to be opened up. Bleeding was found to be coming from the arytenoid cut surface, and was arrested with some difficulty by forceps. The thyroid was again approximated and the neck wound closed, the tracheotomy tube being retained for twenty-four hours. Convalescence was uninterrupted, and now, eight weeks later, the interior of the larynx appeared quite healed.

The PRESIDENT demonstrated a splint which he had devised for use in the operation of septal resection, and explained the method of its application. He said that the splint should be left in position for twenty-four hours after the operation. Its use obviated the necessity of plugging the nasal cavities, and in consequence diminished very much the discomfort previously felt by patients during the twenty-four hours following the operation. The splint consisted of two circular leaden plaques about 1 inch in diameter, which were placed on either side of the septal flaps and connected by a stitch through their centres.

Dr. T. O. GRAHAM showed a retrosternal goitre removed by operation from a man aged 54 years. The patient had a history of seven months' dyspnoea and inspiratory stridor. A diagnosis of calcified retrosternal thyroid enlargement was made by *x* rays. The extension was removed through a transverse incision above the manubrium sterni. The growth, which was about the size of a cricket ball, was easily shelled out of its loosely attached capsule. Immediate and complete relief of symptoms followed the operation.

The PRESIDENT read a paper entitled "A retrospect of laryngology." He said that, in general, laryngology was still in its infancy. The invention of the laryngoscope in 1855 by Garcia had thrown a flood of light on conditions previously only guessed at. In the course of a long and interesting paper, Sir Robert Woods mentioned many of the fantastic theories of disease which were held in the early days of the specialty. Gout and tobacco were the favourite scapegoats for conditions the causes of which were not understood, and therapeutics were confined to the local application of astringents and caustics. He traced the evolution of many operations, such as those for the removal of adenoids and for the relief of empyema of the maxillary antrum, and described the introduction of many therapeutic agencies such as diphtheria antitoxin and salvarsan, which were at first severely criticized, but were now generally admitted to be of great value. There were still many conditions in which further investigation was required—for example, ulcerative diseases of the nose, of which the classification might not yet be complete. Further division might be required in the classification of malignant granulomata of the nose, first described by himself in 1921. Here was a disease pursuing a well-marked and deadly course, clinically unique, and yet its only histological feature consisted in the formation of granulation tissue which might well come from a wound in the process of ordinary healing.

At a meeting of the Newcastle-upon-Tyne and Northern Counties Medical Society on January 8th, with Mr. T. A. HINDMARSH in the chair, a discussion on artificial pneumothorax was opened by Dr. T. C. HUNTER and Dr. W. H. DICKINSON, the former giving a brief history of the operation and a survey of the more salient features of the technique. Pleural shock and other complications were dealt with at length. Numerous slides and *x*-ray films were exhibited, notably those showing adhesions preventing complete collapse of cavities. The importance of earlier operation was emphasized. Dr. Dickinson reviewed more particularly the practical points in the selection of cases, and discussed the technique, duration, and results of collapse therapy. He gave a demonstration of the apparatus used by him, and insisted upon the necessity of radiological control before and during treatment. In addition, he recounted some of his experiences with the method in non-tuberculous diseases of the lungs—for example, bronchiectasis and pulmonary abscess—and mentioned its usefulness in the diagnosis of obscure chest conditions. He emphasized the value of artificial pneumothorax to patients suffering from repeated and severe haemoptyses, and expressed the opinion that complete cures could only be expected in reasonably early cases free from serious complications, notably abdominal tuberculosis. A discussion followed in which many members took part.

At a meeting of the London Association of the Medical Women's Federation on January 27th, with the president, Dr. LETITIA FAIRFIELD, in the chair, Miss MILDRED WARDE read a paper on the uses and limitations of operations on the ear. After dealing with several minor surgical conditions, Miss Warde said that in acute otitis media paracentesis was indicated as soon as the drum showed bulging; the incision should be vertical, behind the handle of the malleus, and should reach to the floor of the meatus. There was considerable risk that only a small part of the diamond-shaped knife would actually perforate the tympanum; the operation should be repeated if necessary. In acute mastoid inflammation signs and symptoms might be equivocal when the mastoid cells were full of pus. If no focus could be found in the naso-pharynx, operation should be advised in cases of treated, but persistent, nasal discharge lasting over a fortnight. In dealing with chronic discharging ears, the speaker recommended, in cases of marginal perforations with granulations, the radical mastoid operation when dead bone was present; otherwise the conservative methods of cleansing, and the application of caustics, were satisfactory. In cases of acute labyrinthitis sedative treatment was best, but meningitis was a dangerous complication resulting from the presence of a dead labyrinth. She stressed that labyrinthine function should always be tested before a mastoid operation was performed. Replying to questions, Miss Warde favoured ionization in the treatment of chronic ear discharge in children, and mentioned that it was essential to have every part of the ear full of lotion in order to produce an absolutely sterile cavity by coagulation of the whole surface layer.

Reviews

RADIUM THERAPY

Dr. G. E. BIRKETT, in his *Radium Therapy: Principles and Practice*,[1] has embodied the result of the extensive experience he gained during the last few years as radiologist to the Manchester and District Radium Institute. The work he has done there is widely known, and he writes as one of the leading authorities on the treatment of cancer of the tongue and mouth, a subject to which a considerable part of the book is naturally devoted. His book traverses necessarily, very much the same ground as that published by Mr. Stanford Cade in 1929, and is conceived on much the same plan. Radium therapy is, however, still in a fluid state, and we may with profit read a new authoritative pronouncement on the subject at least once every two years. By a very sad coincidence Dr. Birkett (as recorded elsewhere) has died at the early age of 37, within a few weeks of the publication of this account of his methods and experience.

The author describes first the general principles of radium therapy and the protection of radium workers. He has some interesting remarks on the selection of patients for radium treatment, and deprecates both indiscriminate treatment of hopeless cases and indiscriminate biopsies of all malignant tumours. The first leads to disappointment and discredits the method; the second is biologically unsound, so that it is better, if necessary, to make a small percentage of errors in diagnosis. There is a short chapter on radium burns and radium necrosis, which is one of the chief dangers of unskilled treatment. The longest chapter (44 pages) deals with the treatment of buccal carcinoma. Dr. Birkett agrees with other observers that some of the most rewarding work can be done in this region, and he himself has obtained some 45 per cent. of five-year cures. He still advocates thorough block dissection of the neck as the best treatment for the secondary glands.

Dr. Birkett's experience of the use of radium in other parts of the body is not so large, and he refers extensively to the work of others, so that a useful review is obtained of the methods employed and the results obtained in all parts of the world. In the treatment of carcinoma of the breast he favours implantation of needles in the axilla through a wide incision, though other workers have not thought this to be necessary. The later chapters deal with carcinoma of the cervix, which is treated at Manchester by both cavitary application and implantation; carcinoma of the rectum, where results have been disappointing; epithelioma of the skin; and rodent ulcer, where results are good; and urogenital carcinoma, where results are still uncertain. Sarcomata, cerebral tumour, and a few others are dealt with very briefly. The book is well and simply written, there is a good index, and the illustrations are excellent.

DIAGNOSIS OF MENTAL DEFICIENCY

As stated in the preface, Dr. HERD'S book on *The Diagnosis of Mental Deficiency*[2] is not intended to be a complete textbook, nor to cover the subject in all its aspects. It is therefore perhaps necessary to point out that, for diagnostic purposes, defectives fall into two groups, each being defined by a separate Act of Parliament. The first group consists of children between the ages of 7 and 16 years; they are defined by the Education Act, and diagnosis and certification are needed to secure their admission to special schools. With these the general practitioner, as such, has nothing to do, the duty being performed by a specially appointed medical officer of the Education Authority. The second group consists in the main of those children and adults who are below and beyond these ages; these come within the provisions of the Mental Deficiency Acts, and the general practitioner is frequently consulted regarding them. This book is written from the point of view of the school medical officer, and, whilst dealing to some extent with the second group, it is mainly concerned with the diagnosis of children of school age.

After a brief but readable outline of the psychology and mental development of the child, the major part of the book is concerned with an account of the various tests made use of in diagnosis. The author rightly insists upon the fact that an accurate diagnosis can only be arrived at after consideration of many data, and that the importance of the mental ratio is very apt to be greatly overestimated. In addition to this he gives a good deal of general information which cannot fail to be of value to the newly appointed school medical officer, and from this aspect it should prove a useful publication. One is left with a feeling of regret that Dr. Herd did not confine himself to this section of the subject, for when he ventures into the wider realm of those defectives who come within the purview of the Mental Deficiency Acts he is on less sure ground, and his account is too sketchy to be of real service to the general practitioner. A special chapter is devoted to moral defect; but it is doubtful whether it will be of assistance in clarifying our concept of this difficult subject. The author doubts whether defect of that department of the intellect known as "wisdom" occurs in the moral defective. But the essential characteristic of these persons is that they persist in their misconduct in spite of repeated punishment and of disadvantages which would be obvious to a person of normal intelligence. It seems impossible to regard such persistence as merely due to an imperfect development of the higher social or moral sentiments without any involvement of some factors of the intellect. It is, indeed, the presence of such an intellectual defect which distinguishes the curable criminal and psychopathic delinquent from the absolutely incurable moral defective.

URTICARIA

That baffling disease urticaria is the subject of an interesting volume[3] by Dr. E. JOLTRAIN, a physician proud to acknowledge himself a pupil of the late Professor Widal, to whom the book is dedicated and of whose life and career an account is given by way of preface. Dr. Joltrain furnishes a complete description of the various clinical varieties of urticaria, not forgetting the lichen urticatus or strophulus of infants, a condition not exactly identical with urticaria as found in adults, though without doubt a closely allied phenomenon. As might be expected from his intimate association with Widal, the author attaches great importance to the phenomenon known as haemoclastic shock. This phenomenon, first described by Widal in connexion with paroxysmal haemoglobinuria, is marked by three characteristics—namely, a sudden leucopenia, an increase in the blood coagulation time, and an appreciable fall in blood pressure. Similar events also occur at the onset of an urticarial attack, and they also are caused by the injection of certain peptones, so Joltrain regards urticaria as a shock or anaphylactic phenomenon due to the liberation of some similar substance either derived from food or

[1] *Radium Therapy: Principles and Practice.* By G. E. Birkett, M.C., M.R.C.S. London: Cassell and Co., Ltd. 1931. (Pp. x + 186; 52 figures, 19 plates. 17s. 6d. net.)

[2] *The Diagnosis of Mental Deficiency.* By Henry Herd, M.B., Ch.B.Ed. London: Hodder and Stoughton. 1930. (Pp. xi + 272; 33 figures. 12s. 6d. net.)

[3] *Les Urticaires.* Par Édouard Joltrain. Paris: G. Doin et Cie. 1930. (Pp. iv + 417; 8 figures, 8 plates. 40 fr.)

produced in the course of a slightly deranged metabolism. Hence, travelling by a somewhat different route, the author arrives at the same conclusion as other observers, that urticaria is one of the manifestations of allergy.

The chapter on therapeutics is adequate, and includes all methods of treatment which have any claim to efficacy in the control of urticaria. When the condition can be shown to be due to any specific poison, whether of food or other origin, treatment is comparatively easy, and consists either in avoidance of the *fons et origo mali* or in specific desensitization; when, however, there is a general sensibility the problem is much more difficult. The methods recommended consist either in the regulated ingestion of small quantities of peptone, intravenous injections of small quantities of a strong solution of sodium bicarbonate (a method not without its disadvantages) or of magnesium hyposulphite. Dr. Joltrain mentions also the procedures of autohaemotherapy, blood transfusion, serotherapy, and other methods which have been tried. But the problem of the successful treatment of urticaria still remains unsolved.

As a summary of the present state of our knowledge of the disease this book is well worth reading.

THE CLINICAL CLERKS' GUIDE TO WISDOM

Dr. GEOFFREY BOURNE'S *Introduction to Medical History and Case Taking*[4] is an example of how much the text of a book may surpass its title; for it contains, in addition, much sound instruction on diagnosis, prognosis, and treatment. The first half of the title is indeed a little ambiguous, as it is nearly the same as the whole title of Lieut.-Colonel F. H. Garrison's wonderful book on the history of medicine. Gracefully dedicated to his former teacher Dr. J. H. Drysdale, this guide-book for medical clerks reflects much of the logical influence which "stimulated a quarter of a century of student education" at St. Bartholomew's Hospital. After describing how to take the history of a case, and showing the difficulties in obtaining a correct statement from an unskilled observer, and concisely setting out the details of how systematically to examine a patient's physical signs, the author proceeds to what is the best part of an admirable and somewhat unusual book—diagnosis. At the present time laboratory tests bulk so large, especially to students with little confidence in their powers of physical diagnosis, that the chapter on the place of laboratory methods in diagnosis is most appropriate, for it critically discusses their value and limitations. The book is written with an epigrammatic touch and in an attractive style by no means universal in books on this subject; thus the estimate given of diagnostic clinics under the leadership of a "diagnostician" aptly quotes Macheath's dictum in *The Beggar's Opera*, "few purses can support the expense of dying like a gentleman." There is a refreshing freedom from dogmatism in the illustrative cases quoted, and there is a useful and full record of a case describing the procedure adopted in formulating the diagnosis. The final sections on prognosis and treatment are similarly characterized by broad-minded wisdom.

MOTHERCRAFT IN INDIA

In his preface to *The Expectant Mother and Her Baby*,[5] Dr. BODH RAJ CHOPRA states that his book is intended "to minimize the appalling waste of human life caused through infant mortality, which still remains one of the saddest features of the present day life of India. . . ." He has addressed his information to the Indian mother in particular, and the chapters are set out clearly and simply; the subject-matter is practical, covering the care of the expectant mother and of the newborn infant, breast-feeding, wet-nursing and artificial feeding, common ailments of infancy, and the care of the mentally deficient child. The aim of the whole book is to focus the mother's faith in common-sense measures rather than superstitions, and in the family doctor as opposed to the local wizard. Read carefully, and followed, his sound advice should have an enormous influence on the care of children in the East, but it is doubtful whether one volume can play more than a small part in breaking down the superstition of centuries; even so, its value is obvious. The arrangement of the book is easily followed, but occasionally two paragraphs on the same subject are divorced by other matter, so that a certain amount of repetition becomes necessary. The chapter on artificial feeding deals with the question of obtaining clean milk, and with the relative advantages of cow's, goat's, and ass's milk; the importance of fruit juice in the diet of the artificially fed infant is emphasized, but there is no reference to the use of cod-liver oil; rickets, however, Dr. Chopra finds, is less common in India than in European countries. In an early chapter certain precepts are quoted from Charak, a sage of ancient India, which, as Dr. Chopra remarks, "may not appeal to modern scientists, but . . . deserve to be closely analysed and examined before a final verdict may be pronounced upon them." Most of these precepts are concerned with the diet of the mother, and the warnings are undeniably sound, although the reasons given are more often impressive than accurate. No amount of analysis, however, appears to justify the alarming statement that "a woman who is fond of pork brings forth a child that is of bloody eyes, or that becomes subject to asthma, or that has hair exceedingly hard." Altogether more acceptable to the modern mind is another of Charak's observations: "A woman who drinks spirituous liquors brings forth a child that becomes always thirsty and has a mind destitute of firmness."

NOTES ON BOOKS

It is apt to be forgotten that a considerable area of the United States is tropical or subtropical, and that many of the diseases which the physician in this country scarcely ever sees—hookworm, malaria, pellagra, sprue, and so on—are endemic there and sometimes very serious. Dr. ALFRED C. REED has now provided the American physician with a handy textbook[6] dealing with these diseases, which are generally considered exotic, but which, in these modern days of swift transport, may at any time come within the purview of the practitioner in any part of the continent. Diseases never encountered in America are not discussed, and those confined to South America are only reviewed in their essential features. The volume should usefully fulfil its intended function; but its value outside North America is limited by the restrictions imposed upon it by the author.

The proceedings of the Fourteenth Northern Congress for Internal Medicine,[7] held at Helsingfors from June 28th to 30th, 1929, have recently been published as Supplement XXXIV of *Acta Medica Scandinavica*, under the editorship of the general secretary, Dr. E. HISINGER-JÄGERSKIÖLD. The congress consisted of physicians from Denmark, Norway, Sweden, and Finland, but as is the rule of the *Acta Medica Scandinavica*, their communications are published in English, French, or German. The

subjects chosen for discussion included the treatment of arthritis, the diagnosis of myocarditis, pernicious anaemia, the determination of blood sugar, treatment of diabetes, metabolism of school children, and goitre in Finland.

The publication of the *Trial of George Chapman*,[8] edited by H. L. ADAM, recalls some instructive examples of failure to diagnose antimonial poisoning. In 1903 Severin Klosowski, *alias* George Chapman, was found guilty at the Central Criminal Court of the murder of Maud Marsh. As the trial has considerable medico-legal interest it is worth outlining the main circumstances of the case. The woman was first seen by a doctor on October 10th, 1902, when she complained of great pain in the abdomen, vomiting, and diarrhoea. It was thought that she might be suffering from gastro-enteritis. A diagnosis of peritonitis had previously been made at Guy's Hospital. On her condition becoming worse another doctor was called in for consultation, and examination suggested that the symptoms were caused by an acute irritant poison, probably ptomaine. Later, on the same day, it occurred to one of the doctors that the symptoms might be due to repeated doses of arsenic, but the patient died the following day, before this opinion was expressed. Chemical analysis of the viscera showed traces of arsenic, and Chapman was arrested on October 25th. Subsequent analyses of various parts of the body proved conclusively that death had resulted from impure antimony containing arsenic. The amount was estimated at more than 20 grains. Police investigations then disclosed that two other women with whom Chapman had lived had died in similar circumstances, and their bodies were exhumed. Although five years had elapsed since the burial of Spink, his first victim, the body was remarkably well preserved; "the face and head were those of a woman who might have been coffined that day." Analysis revealed that antimony had permeated the muscles of the thigh. Death had been certified as due to phthisis. The body of Bessie Taylor, whose symptoms had been diagnosed by different doctors as hysteria, cancer, and uterine disease, was also well preserved. Antimony found in the viscera amounted to over 29 grains. The death certificate recorded intestinal obstruction, vomiting, and exhaustion. In his summing-up Mr. Justice Grantham remarked that it was the duty of a practitioner to consider the possibility of other causes when a natural disease failed to react to known remedies.

In a paper read before the International Congress of Malariology at Algiers last May, and published as a Supplement to the *Rivista di Malariologia*, Professor A. MISSIROLI gives an interesting account of the antimalarial campaign in Italy by drainage of the soil followed by intensive cultivation. Special reference is made to Rome and the delta of the Tiber, which includes Ostia, Isola, Sacra, and Maccarese.

The Health Resorts Section of the current *Medical Directory*, edited by Dr. R. FORTESCUE FOX and published as *An Annual Guide to the Spas and Marine Health Resorts of Great Britain and Ireland and New Zealand*,[9] gives up-to-date information about these watering places, their climates, and clinical indications. Lists of hydros, hotels, etc., are appended.

The Minutes of the Dental Board of the United Kingdom and of its Various Committees for the year 1930 have been published[10] with ten appendices, which include reports of the Dental Health Education Committee and of the Examination, Education and Research Committee. The *General Index*[11] to the minutes of the Dental Board from 1921 to 1930, relating to volumes i to ix, has also been issued.

PREPARATIONS AND APPLIANCES

SELF-RETAINING GAG AND TONGUE TRACTOR

Dr. W. T. MILTON (London) writes: The gag shown in Figure 1 is the outcome of a remark made by Mr. A. M. Zamora with regard to the advisability of sending patients back to bed efficiently gagged after operations on the nose and throat. It occurred to me that none of the gags in general use were of a type suited to this purpose, in that they were mostly furnished with projecting handles, which, when in contact with the pillow or bedclothes, would tend to dislodge the gag. Furthermore, they could not be spared from the operating theatre. The gag which Messrs. Down Bros. have very successfully made for me obviates these difficulties. It is constructed of endless spring wire, fitting closely around the mouth, with finger plates and dental props in one. The advantages claimed are: (1) ease and quickness of introduction and withdrawal with one hand; (2) the gag is self-retaining

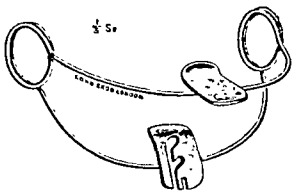

FIG. 1.

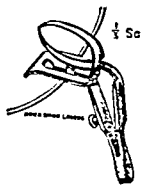

FIG. 2.

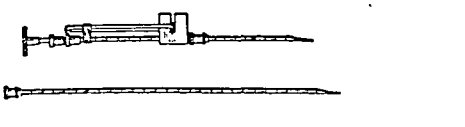
and is not easily dislodged; (3) the mouth aperture is sufficiently wide to permit of a generous airway, and to allow swabbing of blood and mucus, and not wide enough to cause any respiratory embarrassment; (4) there are no projections likely to catch on the bedclothes, inasmuch as the finger plates are central and the lateral springs lie flat against the cheeks. I have also found the gag very useful during the administration of anaesthetics in other than throat cases, particularly in those edentulous subjects whose flapping lips and cheeks so often hamper the anaesthetist. When used in this way the distance between the finger plates constitutes a helpful indicator as to the degree of muscular relaxation. With deep anaesthesia and fully relaxed musculature the finger plates are at their maximum distance apart, which distance gradually diminishes as the masseter muscles come into action once more with a lessening depth of anaesthesia.

Messrs. Down Bros. have also made for me a tongue tractor (Fig. 2) for use in conjunction with the gag. This, when anchored in the slot cut in one of the finger plates, is self-retaining. To obtain the maximum effect the tongue is secured in the clip and the latter drawn forward sufficiently to allow the narrowed neck of the clip to be slipped into the central slot. Lesser degrees of traction can be secured by engaging the stud on the under surface of the body of the clip in either the central slot or one of the deeper ones. I fancy that this gag may prove a useful addition to the midwifery bag for service in those very frequent cases where the practitioner has to rely on the services of the nurse or midwife for the maintenance of anaesthesia.

A RADON SEED INTRODUCER

Dr. R. T. BRAIN (Skin Department, London Hospital) writes: The instrument illustrated was designed primarily for



the hypodermic implantation of the small metal tubes 1 cm. by 0.11 cm. known as radon seeds. It has a miniature magazine of machine-gun type, which automatically feeds the seeds into the lumen of the introducing needle by means of a spring arm. Needles of different lengths, marked in centimetres, can be screwed on to the magazine mechanism, so that the introducer is equally serviceable to the surgeon. The magazine illustrated holds six seeds, and the capacity is suitable for skin work. Larger magazines can be supplied to order. The instrument may be obtained from the Medical Supply Association, Ltd., 167-185, Gray's Inn Road, W.C.1.

British Medical Journal

SATURDAY, FEBRUARY 14th, 1931

A STUDY IN NUTRITION

It used to be said that half the world never knew how the other half lived. It may be a sign of the times that each half is now, in various ways, being given an opportunity of enlarging its knowledge in respect of its neighbours. If one such opportunity is to be seized, the report by Professor E. P. Cathcart and Dr. A. M. T. Murray on an inquiry into the diet of 154 families of St. Andrews should be read. It has just been issued by the Medical Research Council.[1] A scrutiny of other people's larders and housekeeping arrangements may not be altogether edifying or pleasant; it may provoke envy or a certain discomfort, and for that reason it is, as a rule, discouraged. Nevertheless, it is good sometimes to take stock of the situation of our fellows as well as of our own. If we happen to be interested in the theory of dietetics, it is profitable to see how the ordinary person puts dietetics into practice. We may be able to give him good advice; on the other hand, we may find it desirable to modify our theory. Professor Cathcart and Dr. Murray have, as it were, focused a camera on a vertical slice of society and have preserved for us a picture showing the family commissariat at all stages of the social scale. There is, perhaps, nothing very new or very startling to be seen in the picture, now that it is developed and printed. The care and labour involved in the development, the effort to get the negative as sharp as possible and yet avoid all "touching up," can be appreciated only by those who have themselves been engaged on similar work. One or two important points, however, stand out clearly from the picture, and at least one consideration emerges that will prove of importance to future workers.

The population under review embraced occupations (and therefore economic levels) from "professional" to "unemployed." It was found, as had been disclosed by earlier investigations, that the less money the family had with which to purchase food, the more advantageously was it laid out as regards return of caloric value and protein per penny spent. Thus, the professional man whose family spends 18s. 3d. per man per week on food buys calories at 121.2 to the penny, while the "unemployed" who spends 6s. 1¾d. buys them at 201.2. It should be explained, perhaps, at this stage, that all the figures are worked out on a basis of "man value." Various investigators have constructed tables in which the food requirements for various ages of both sexes are worked out on the basis of 1.0 for a man. An adult woman thus stands, according to Lusk, at 0.83, a child between the ages of 6 and 10 years at 0.60, and so on. As a matter of fact, the authors find reason to doubt the accuracy of the figures at present generally accepted, and, on the basis of data which they have collected, they present an alternative scale in which the coefficient for an adult woman is considerably lower (0.70). On the other hand, that for a growing child is rather higher.

Another point that emerges from this study, as from others, is the manner in which, when times are bad, every effort is made to prevent the lowering of the father's diet. This results, as the figures clearly show, in the breadwinner eating very definitely at the expense of the rest of the family, particularly at that of the wife. How far this state of things is the outcome of conscious and deliberate arrangement it is difficult to say; it is equally difficult to deny its logic. Obviously, the earning power of the head of the family must be kept up at all costs or things can only go from bad to worse. The realization that such arrangements, conscious or unconscious, are necessary on the part of any large number of persons is salutory, if not altogether pleasant, for such of us as are in danger of forgetting about the other half of the world and its way of living.

A subject for special comment by the authors is the relatively high caloric intake—the "luxus" consumption, as it is called—on the part of the well-to-do. The well-to-do, in point of fact, do not get fatter than other people, and this extra consumption is ascribed chiefly to the deliberate taking of exercise, and their consequently improved physical condition. It is pointed out that, on the law of surface area, that part of the population which possesses the best physique will have the highest standard metabolism. It is also suggested that deliberate "exercise" is often more exhausting than are pursuits usually regarded as hard manual labour. With regard to the poorer families, the authors emphasize the very great influence of the "good" and "bad" housekeeper respectively on the standard of living. A fact that stands out very clearly—and is, indeed, singled out for remark in the preface—is the high consumption of fat by all the sections studied. Much more fat is eaten than is to be expected from the hitherto accepted figures for the usual distribution of foodstuffs in the diet. The matter is of considerable interest, and makes us anxious to see similar studies undertaken in other parts of the country. We should like to compare these Scottish figures with those obtained, say, in Berkshire and in Cornwall.

There can be no doubt about the interest and importance of studies such as these; and their interest and importance will increase as they are multiplied, and made to cover wider and more diverse areas of the country, so that comparisons can be drawn and statistical conclusions made more reliable. The plan adopted of studying a vertical slice of the population covering all levels of income clearly has many advantages over that of confining attention to a horizontal layer—one particular trade or occupation.

TUBERCULOSIS OF THE EAR: FRONTAL SINUSITIS

The Sections of Otology and Laryngology of the Royal Society of Medicine met in the morning and afternoon of February 6th. In the morning the subject for discussion was tuberculosis of the ear. Mr. F. C. Ormerod and Sir StClair Thomson gave detailed accounts of their experience of this manifestation of tuberculous disease at the Brompton Hospital and at King Edward VII Sanatorium, Midhurst, respectively. The disease seen in adults in these circumstances differs from the primary aural tuberculosis of childhood, a condition characterized by a profuse watery discharge, enlarged cervical glands, and sometimes facial paralysis, and only amenable to very radical surgical treatment. Both speakers were agreed that the incidence of tuberculous otitis media is something under 2 per cent. in phthisical patients. Such patients almost invariably have tubercle bacilli in the sputum, but it is not always easy to find them in the aural discharge. Deafness is an early symptom, and there is a remarkable absence of pain, fever, or profuse discharge. In cases arising under the conditions mentioned it has been possible to observe the onset of the disease before perforation of the tympanic membrane has occurred. There is no congestion or tension, but the membrane loses its normal pearly appearance and becomes dull and sodden. No paracentesis is required and perforation occurs painlessly. The multiple perforations, which have been considered so characteristic, are exceptional. When they do occur two may be observed to coalesce and form one large perforation, leading in the end to total destruction of the membrane. Exfoliation of the ossicles, facial paralysis, and extensive caries of the temporal bone are scarcely ever seen under the conditions in which these observations were made, and only simple treatment is required. The ravages which result when children are attacked, and which were also described by Politzer in patients who had died from phthisis, do not seem to occur. Although not in itself often fatal, the condition is nevertheless serious, because it indicates either a low resistance or a severe infection, or both. In a proportion of the patients the larynx has already been attacked and the majority have succumbed to the pulmonary disease within three years.

In the afternoon the Section of Laryngology discussed the treatment of frontal sinusitis. Many patients were exhibited, and they served to show that there is no general agreement about the best method of operation. The Killian "bridge" operation, however, appears to have been abandoned. Dr. J. S. Fraser and Mr. J. P. Stewart gave a careful statistical survey of several groups of cases observed in Edinburgh over a long period of years. The conclusion seemed inevitable that when external operation is required the best and safest results are obtained by a complete obliteration of the sinus, although the cosmetic effects are some disadvantage. Mr. Howarth, however, has shown that a less radical operation for drainage of the sinus can produce uniformly satisfactory results, and he described his operation, which consists in removing the floor of the frontal sinus and converting the ethmoidal cells and frontal sinus into a single cavity which can drain freely into the nose. This operation has found many supporters during the last ten years, and has been further improved by lining the new fronto-nasal duct with a Thiersh graft. Mr. Douglas Harmer exhibited a number of patients who had been treated for frontal sinusitis by intubation, and gave an analysis of sixty-three cases. A small incision is made below the inner end of the eyebrow and the sinus is opened above the supra-orbital ridge. A soft rubber catheter, to intubate the infundibulum, is drawn up from below through the nose and anchored externally on the forehead. In cases of chronic sinusitis the patient must wear the tube for several months, but it can be replaced at intervals by one of a larger size, so that a process of gradual dilatation is induced. The method is designed to provide free drainage and ventilation both externally an internally; and to dilate the fronto-nasal duct without damaging its lining membrane. In the patients exhibited there was a remarkable absence of scarring and deformity. The discussion, however, showed that there is still no settled opinion on the relative merits of intranasal and external operations. Nevertheless, the swing towards intranasal operations seems to have reached its limit, and the time is approaching when each case will be treated by the appropriate operation and not according to the prejudice of the party to which the operator happens to belong. At present rhinologists are still divided into "intranasalists" and "externists."

RECURRENT DISLOCATION OF THE SHOULDER

There is an old therapeutic maxim of two words: "Tolle causam!" It conveys excellent advice, but unfortunately the cause of a malady cannot be removed for certain until it has been identified. In the case of recurrent dislocation of the shoulder there is no consensus of opinion about its cause, and it is therefore not surprising to find that the methods advocated and employed for its cure are various, and their results uncertain. Last June Dr. Melvin S. Henderson of the Mayo Clinic, Rochester, read a paper before the Orthopaedic Section of the American Medical Association[1] on the results of treatment of habitual dislocation of the shoulder, especially by the teno-suspension operation, in which he was able to report excellent results. In the admirable report on this subject by Dr. Tavernier of Lyons, which we summarized sixteen months ago,[2] the pathological anatomy as far as it is known was fully described, and elongation of the coracoid process recommended as the best remedial operation.

Broadly speaking, the liability to recurrent dislocation without violent trauma has been ascribed to congenital bone defect, to laxity of capsule, or to injury

[1] *Journ. Amer. Med. Assoc.*, November 29th, 1930, p. 1653.
[2] *British Medical Journal*, October 18th, 1929, p. 732.

of the glenoid cavity, including detachment of the capsule and glenoid ligaments. Each operator, according to his own view of the pathology, has advocated an operative proceeding designed to remedy the supposed defect, and most operators have been able to claim good end-results in a certain number of cases. Dr. Melvin Henderson tabulates forty operations on thirty-seven patients, twenty-four of which resulted in cures, and among which the ten cases of teno-suspension were all successful. This operation, as described by him, consists in excising a strip of the tendon of the peroneus longus muscle amounting to half of its width, and with it forming a new ligament of the shoulder-joint attached through drill holes in the acromion process and the head of the humerus, thus forming a suspensory ligament which does not hinder abduction but prevents undue descent of the head of the humerus. These results, though only yet observable on a small number of cases, are most encouraging, for the operation is safe and comparatively simple; but Tavernier has reported equally striking results from the coracoid operation of Oudard, a proceeding devised with a different objective. Henderson states his belief "that the large majority of habitual dislocations is due to laxness of the anterior inferior portion of the capsule," but he frankly admits that when performing capsulorrhaphy he has been unable to demonstrate such laxity. He adds this significant statement: "It is difficult to produce a dislocation by passive motion in a case of habitual anterior dislocation, even when the patient is anaesthetized. I have tried to do it in a number of instances and succeeded only once. Voluntary muscular action is necessary, such as takes place when the shoulder assumes the position of forward abduction, a weak part in the capsule permitting the head to luxate."

We may be permitted to suggest that the *causa causans* of habitual dislocation is irregular or ill-co-ordinated and violent muscular action taking effect on a weakened joint apparatus. The occurrence of the lesion in epileptic seizures points to this conclusion. Those operations which have hitherto been successful act by preventing extreme ranges of movement. Among these, teno-suspension as described by Dr. Melvin Henderson appears to be simpler, less liable to complications, and more effective than operations on the bones and muscles as hitherto practised.

THE INDIAN MEDICAL SERVICE

The proposals of the recent Round Table Conference with regard to the Indian Medical Service seem to have passed almost unnoticed amid the sweeping changes in Indian government so closely discussed for nine weeks at St. James's Palace. Indeed, the I.M.S. scarcely came into the picture, save for a few observations in the Committee on the Services, which was charged with the consideration of the five or six civil services in India. Some of the Indian speakers took occasion to point out what they considered to be anomalies in the Indian Medical Service, and pleaded for the separation of the military from the civil side, the recruitment for the former to be partly in Great Britain and partly in India, but the recruitment for the latter to be wholly in India. It was also, we understand, the strong view of those who took this line that the control of the Provincial Governments over the medical service should be not less complete than over the other branches of the civil administration. One prominent Bombay representative, while admitting that during the ten years since the previous reforms the position of Indians has improved, declared the point of irritation to be the order of the Government that there must be in certain districts, acting as civil servants, European members of the Indian Medical Service. The view of some of the Indian delegates was that the Government was doing right to ensure that qualified medical practitioners were available—by whom, apparently, were meant men with European qualifications—but that there should be no distinction between Indians and Europeans. The European qualification was desirable, but not necessarily the European practitioner. The Government, they said, would be able to meet all its requirements, if necessary, from members of the Indian medical profession holding European qualifications, including the highest qualifications obtainable in this country; numbers of such men were available in many parts of India, only too willing to do Government work. It is the distinction, not between a Bombay degree and a London degree, but between a brown skin and a white, which wounds the Indian amour-propre. The report on the Services, presented to the main conference by Sir William Jowitt, the chairman of the committee, was only a summary of the views which had been expressed. It stated the committee's opinion to be that, subject to the maintenance of the rights and safeguards of all persons appointed before the new constitution comes into force, there should in future be no civil branch of the I.M.S., and that no civil appointments, under the Government of India or the Provincial Governments, should in future be listed as reserved for Europeans as such. It was further laid down that the civil medical service should be recruited through the public service commissions, operating either on behalf of the Government of India or the Governments of the Provinces, and that these commissions, like their respective Governments, should bear in mind the requirements of the Army and of British officials in India, and take steps to recruit a fair and adequate number of European medical men to the civil medical services. It was also suggested that the Provincial Governments, in selecting their European doctors, should give preference to those members of the I.M.S. who had undertaken a period of service in the Army. Two members of the committee, Lord Zetland and Sir Edgar Wood, expressed a fear—and their riders were added to the report—that under the scheme proposed neither the Provincial Governments nor the I.M.S. would secure European medical officers of the type required; these two members preferred that the present arrangement should continue until Indianization, both in the Indian Army and in the Civil Services, had proceeded further. One provision laid down was that in all the Services, including the I.M.S., there should be suitable safeguards embodied in the new constitution for the payment of pensions and provident funds, and that steps should be taken to reassure existing members of the Services, so that they might continue to serve with loyalty and efficiency for their normal term.

ATMOSPHERIC POLLUTION AND PULMONARY DISEASES

Although the inquiry into the cause of the sixty-three deaths which occurred during the first three days of last December in part of the Meuse Valley has not yet been completed, a correspondent in Belgium has supplied certain details which have an obvious bearing on the incident. He points out first that the majority of those who died were elderly, and in many cases were already suffering from cardiac and pulmonary disorders. Some local medical authorities at the time, and later, held the view that the deaths were thus not altogether surprising, in view of the bitter cold and the misty atmosphere, but Professor Nolf, president of the Belgian Red Cross Society, declared emphatically that in his opinion the fog as such, and even if of an unusually low temperature, could not possibly have caused so abrupt and localized a mortality. This opinion has now received support from other quarters. A point which has been overlooked by many commentators is the surprisingly short interval between the onset of the first acute respiratory embarrassment and the subsequent death, a phenomenon suggesting poisoning rather than cardiac or pulmonary depression. Post-mortem examinations were made at once in several cases, but the results were not published until recently, when an interim report of the commission of inquiry revealed the not unexpected fact that the victims' lungs showed irritative changes consistent with the inhalation of sulphur dioxide—a gas which had been suspected by some from the very first. The sudden disappearance of the fog on the fourth day prevented any analysis from being made, but laboratory researches have been in progress, consisting of the preparation of artificial fume-laden fogs, and the observation of their effects on animals. Professor Firket, president of the commission of inquiry, in his determination to secure that the fullest possible light should be thrown on the disaster, invited Professor Storm van Leeuwen of Leyden to make a special investigation, and the results of this are detailed in the *Münchener medizinische Wochenschrift* of January 9th. The body of evidence now made public suggests that a continual stream of factory fumes was prevented by the fog from escaping from the district; its concentration in the atmosphere steadily increased, therefore, and eventually the limit of human tolerance was reached in some cases. Liège, enveloped at the same time in a dense and extremely cold fog, escaped such a mortality altogether, while the factory village of Engis suffered severely. Professor van Leeuwen, in his closely argued report, shows how the climatological conditions in that small area at that time promoted the increasing accumulation of irritant gases in the air; he cites the precedent of 1911, when a similar though less disastrous incident occurred. He adds, appropriately, that such fatal consequences do not accompany the frequent icy winter fogs of Holland, and that even in ordinary weather the fumes in the air in the Meuse Valley can be perceived by the nose, while the landscape shows abundant signs of their destructive action. The final report of the commission will be awaited with interest, and the possibility of a similar occurrence in comparable districts elsewhere is naturally receiving consideration by public health authorities. For many years it has been urged that there is need of a much stricter control over the smoke and fumes emerging from factory chimneys; the lesson of the deaths in the Meuse Valley may conceivably have a wider application.

ACUTE YELLOW ATROPHY OF THE LIVER

This very fatal disease, which recent British writers (Rolleston and McNee) would prefer to call by the more accurate term "acute necrosis of the liver," continues to be an etiological puzzle. Its incidence has always been peculiar; while as a rule single cases occur at rare intervals to disturb and distress the family doctor, occasional outbreaks of almost epidemic proportions are not unknown. This has been particularly true since the war years, and has affected several European countries, but Great Britain has fortunately escaped. Germany was the first country to take stock of outbreaks of this disease in several widely separated towns, and all sorts of war and post-war conditions were at first blamed. But that the increased incidence of the disease is not confined to nations directly involved in hostilities is shown by the recent monograph[1] of Bergstrand of Stockholm, which, although published in the German language, is concerned with a striking outbreak of the disease in Sweden. Acute yellow atrophy of the liver had been gradually increasing in frequency in Sweden from 1914 onwards, but in 1927 a sudden outburst occurred, resulting in eighty-four deaths throughout Sweden during that year. Forty-two cases were met with in Stockholm alone. The peak of the epidemic was in July, and this seasonal incidence has often been noted before. In 1928 only eighteen cases occurred throughout Sweden up to July, and no recurrence of the diseases in epidemic form has been reported since then. In considering the possible causes of these outbreaks of acute yellow atrophy only one point of importance emerges. The real epidemic is always one of so-called catarrhal jaundice (infective hepatitis), and out of many cases of this kind an odd one progresses to the serious and fatal termination. Indeed, as Bergstrand states, all the evidence points to catarrhal jaundice and acute yellow atrophy being simply different forms of the same hepatic disease. The initial symptoms of the two conditions are well shown by Bergstrand's tables to be identical, and for a week or two there is nothing to indicate to the physician that he is not dealing with a simple case of catarrhal jaundice. Then suddenly the outlook changes, and the signs of total hepatic insufficiency appear—vomiting, delirium, and collapse. Bergstrand, like others before him, was early convinced of the infective nature of the disease, but, like others also, his bacteriological researches yielded nothing. The moral to us in Great Britain is plain. Outbreaks of catarrhal jaundice are common enough, particularly in schools, but fortunately we have been spared so far the epidemic occurrence of acute liver atrophy. In view of what has occurred abroad, it is obvious that epidemic catarrhal jaundice is a condition which must never be taken too lightly, and the liver cells must be protected so far as possible from severe damage by the only remedy at present known to us—the administration of an adequate amount of glucose daily.

[1] *Über die Akute und Chronische Gelbe Leberatrophie.* Von Dr. Hilding Bergstrand. Leipzig: G. Thieme. 1930. (Pp. 114; 68 figures, 2 plates. M.14.)

THE CENSUS OF 1931

In view of the approaching census, which will be taken on April 26th, the Registrar-General, Mr. S. P. Vivian, invited a number of newspaper representatives to meet him last week with a view to explaining the arrangements. Mr. Vivian, who also presided over the census of 1921, is more fortunate than his five predecessors in that, with the growth of popular education, the filling up of a census form should now be within the powers of any citizen. But a period of ten years separating the censuses is too long to permit of any recollection or experience being carried over, or the formation of a "census habit," and so the public has to be carefully instructed every time. It is possible, however, that the capacity of the public has been underrated in the past. It was feared in 1921, for example, that an intelligible and detailed classification of occupations would be unobtainable, but the public were asked to state their occupations in the terms commonly employed in their workshops and places of business, and the results proved not to be disappointing. Some curious tendencies to error manifest themselves in the census returns. One is due to the habit of people of stating their age in round figures, saying that it is 25, for example, when it is anywhere between 24 and 26. Actuarial investigation has shown that by reason of this tendency there is a "heaping up" at the round figures, so that the age of the population is slightly distorted, a fact which may not be unimportant from the point of view of insurance life tables. There is also a tendency not to include newborn infants, perhaps on the supposition that a person who is as yet without a name is one in whom the Registrar-General can take no interest. At all events, the tests applied at Somerset House in previous censuses have shown that a certain number of infants escape enumeration. A provisional report on the results of the census will be issued within two months of the date of enumeration, and the census figures will be published both in county and in national tables. In the county parts will be recorded the housing statistics, while occupational and industrial figures will be given in national tables, though these will be subdivided to show local distribution. Owing partly to the situation created by the Local Government Act, 1929, whereby the allocation of Exchequer grants to local authorities is made on a population basis, a census will, in future, be taken quinquennially. A quinquennial census will have its reaction on the scope of each census, for no one would suggest that the census need be taken twice in ten years with the same degree of detail. Therefore some inquiries are omitted from the impending census, but a new inquiry has been inserted—namely, with regard to permanent residence. Hitherto the "residence" has been that in which the person happened to be lodging on the Sunday night when the census was taken, and every effort has been made to take the census at a time of year and day of week when the people might be expected to be in their own homes. But with the growth of locomotion and the change of social habit, it has become difficult to get a reflection of the nation in residence. If the answers to the question as to permanent abode disclose in many areas wide differences between the distribution in the area and the true resident population, it will be necessary in future to follow the plan employed in many Continental censuses and adopt a resident basis. It is expected that the distribution of the population will show great changes as compared with the census of 1921. These are due to the housing activities of local authorities, the effect of declining industries in depleting the population of certain industrial towns, and the movement back to country from town, as a result of the establishment of factories in rural areas.

TAXATION OF LEARNED SOCIETIES

Recent correspondence on this subject in the *Times* has called attention to the fine line of distinction which seems to be drawn between liable and non-liable societies, and a few comments by way of explanation may not be out of place. The question is, of course, ultimately governed by the statutes as construed by the courts, and the provision into which a society must bring itself to be able to obtain exemption from income tax on its invested funds is so framed as to include societies established for "charitable purposes only." The important words are "charitable" and "only." The meaning applied to the former is a wide one, and has been paraphrased as "beneficial to the community"; it includes such purposes as the spread of religion, the advancement of learning, relief of poverty, and so on; accordingly, the incomes of such bodies as the hospitals, the universities, and the various missionary bodies, are entitled to exemption. On the other hand, the word "only" is obviously very restrictive in its scope, and has been so construed. Until recent years the old-established and well-known learned societies seem to have enjoyed the exemption, but the Board of Inland Revenue contested the claims of various bodies, with the result that in 1928 and 1929 a series of decisions were given in certain test cases, and the present position is ruled thereby. One of the earliest of these cases was that of the General Medical Council, coupled with that of the English Branch Council. It was contended that the statutory nature of their constitution and duties, the important service to the public provided by the maintenance of the *Medical Register*, the publishing of the *British Pharmacopoeia*, and its other activities, brought the Council's income within the statutory exemption. The Court of Appeal held that the Council was not established for charitable purposes only, and was not entitled to exemption. That case was followed by those of the General Nursing Council for Scotland, the Midland Counties Institution of Engineers, and the Geologists' Association, and in each case the claim was refused by the courts. The fundamental difficulty is that where a number of persons mutually combine to explore and discuss professional questions, some advantage is almost sure to accrue to them individually, even though the main—possibly in its origin the sole—purpose of the co-operation is the advancement of knowledge in some special field; and the questions that at once present themselves are, first, does that consideration impose a bar to exemption on all learned societies, and, secondly, if not, how is the line of demarcation to be drawn? The former question appears to be answered by a dictum in the judgement given in the case of the Midland Counties Institution of Engineers: "The question that emerges in all these cases is: Is there so much

personal benefit to the members, intellectual or professional, as to be incapable of being disregarded?" But just how to measure that quantum of personal benefit is a matter on which there is little direct judicial guidance, except, perhaps, that close connexion with a particular profession seems to weight the scales heavily against any society seeking to claim the exemption. This may perhaps explain why the Royal Society is understood to enjoy an exemption denied to the General Medical Council. The influential signatories to a recent letter to the *Times* suggest that the exemption should be extended by legislation "to all societies and institutions whose position and whose work accomplished are recognized as having attained some definite standard of value to the community." Any such expressions would presumably include the Law Society, the leading bodies of dentists, accountants, and other professional men, and might, in these times of unemployment, conceivably be held to include industrial associations which have advanced the interests of British trade at home or abroad. In fact, the question seems to be one on which a precise form of words is unlikely to be devised to meet the views of those who wish to see the exemption widened to the slight extent necessary to cover the cases which have been the subject of judicial decision without being stretched unreasonably. It must be almost universally regretted, for the moderate extension desired would cost the Exchequer but little in tax, and by relieving the societies concerned of a very real burden, would enable them to do greater service to the community. One point should perhaps be made clear. Such societies are not liable to account for income tax on the subscriptions received, but many professional and trade societies voluntarily pay income tax year by year on the unexpended amount of the subscriptions, so that their members may treat the subscriptions which they pay as admissible deductions in computing their own individual liabilities.

MORTALITY FROM INFLUENZA AND PNEUMONIA IN AMERICAN CITIES

A report recently issued by the United States Public Health Service deals with influenza and pneumonia mortality in the fifty cities of the United States that had a population of 100,000 or more in 1910. For thirty-five of these cities, with an aggregate population of nearly 25 million, the numbers of deaths from influenza and pneumonia by weeks are available from September, 1918, onwards. Deaths for the country as a whole are not available by weeks, and so these data for this large group of cities have considerable significance. To supplement them, monthly influenza and pneumonia death rates have been computed for the same cities for the years 1910–18. Since 1915 there have occurred ten distinct periods, each of eight to thirty-one weeks' duration, in which the mortality from influenza and pneumonia in this group of widely separated cities was so greatly increased as to denote epidemic conditions. Minor epidemics prior to the 1918 pandemic occurred in January, 1916 and 1917, and April, 1918, with a very slight rise in the mortality in April, 1915, also. It is customary in the United States to think of the epidemic of 1918 as happening in the autumn, and the enormous peak which occurred in the middle of October has no parallel in any other recorded epidemic. But in addition to this peak, the epidemic stretched out over a period of thirty-one weeks, from September 15th, 1918, to April 19th, 1919, and even as late as the latter part of January, 1920, the mortality from influenza and pneumonia in excess of the expected rates for that season of the year was greater than the excess mortality during the epidemic of 1929. In the early months of 1920 a very sharp epidemic took place, with excess mortality greater than during any other epidemic since the 1918 epidemic. In February, 1922 and 1923, March, 1926, and January, 1929, other epidemics occurred, and in May of 1928 there was a slight rise in the influenza mortality, which extended to many sections of the country. The combined excess mortality from influenza and pneumonia in these six epidemics following the pandemic of 1918 was only about one-half of that of 1918–19.

HARVEIAN SOCIETY CENTENARY

The centenary of the Harveian Society of London is to be celebrated in June, and the following programme has been arranged. The opening meeting, at which an oration will be delivered by Dr. Raymond Crawfurd, will be held on June 11th at St. Bartholomew's Hospital, with Sir Thomas Horder, Bt., in the chair. Ladies will be invited, and it is also proposed to ask delegates from all the medical societies in London and the surrounding districts; after the oration tea will be served and an exhibition of Harvey relics opened. On June 12th the Buckston Browne dinner will be held at the Grocers' Hall, with H.R.H. Prince Arthur of Connaught as the principal guest. On June 13th there will be a pilgrimage to Hempstead Church, Essex, where William Harvey is buried. A short service, conducted by the Bishop of Colchester, is to be held at 12 noon, and on the return journey it is proposed to visit Rolls Park, Chigwell, where Harvey lived at one time. The present owner, Lady Lloyd, has very kindly consented to entertain any members and friends of the society. After tea Sir D'Arcy Power will give a short address on William Harvey's association with Rolls Park.

The disastrous earthquake in New Zealand has aroused world-wide sympathy. It is reported that sanitary conditions, as regards both water supply and sewerage, no longer give rise to anxiety at Napier and Hastings. The Governor-General, Lord Bledisloe, has visited the stricken area, and in a cable to the Secretary of State for the Dominions he says that "medical and relief services have been organized admirably and are working smoothly." The well-equipped field hospital near Napier has evacuated the most serious casualties to other hospitals in North Island. Essential supplies are fairly adequate.

A special joint meeting of the Society for the Study of Inebriety and the Section of Psychiatry of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Tuesday, March 10th, at 8.30 p.m. A discussion on the prevention and treatment of drug addiction (excluding alcoholism) will be opened by Dr. William Brown, Dr. Macdonald Critchley, Dr. E. Mapother, and Dr. F. G. Laughton Scott.

Nova et Vetera

A MAP OF SEVENTEENTH-CENTURY ENGLAND

In his address at the inaugural meeting of the British Medical Association at Worcester in 1832 Sir Charles Hastings spoke of the recently improved facilities of communication between distant towns, both personally and by letter, so that the distance at which members might reside from one another "will oppose but a slight barrier to our undertaking." No doubt he had in mind the improvement of high roads as well as of vehicles, and the organization of the stage coach service. Yet to us, nearly a century later, the means of communication seem to have been terribly slow, just as the velocity of 1931 will probably seem to be snail-like in 2031. In 1832 the stage coach system was at its best, soon to be ruined by railways; yet, even so, the fastest of the regular coach services seldom exceeded nine miles an hour, including stoppages. In "The British Almanac of the Society for the Diffusion of Useful Knowledge" for 1834 there is a list of "Mail Coach Routes Direct from London" which gives the length and the time taken for each stage. From this we learn that the Ludlow and Worcester coach covered the distance of 115 miles from the "Bull and Mouth," London, to Worcester in thirteen hours seventeen minutes, at a rate of rather more than eight and a half miles an hour, including stoppages. It is true that the mail to Edinburgh achieved an average speed of over nine and a half miles an hour, and that in 1824 one of the Bath coaches performed the journey of over 108 miles in eleven minutes less than nine hours, but "the proprietor of the coach very properly admonished the coachman, and cautioned him never again to attempt the same degree of speed" (*Times*, September 3rd, 1824).

Not very long before Hastings spoke the main roads of England were in a condition much inferior to those of the Roman occupation, during which great highways such as the Watling and the Ermine Street were kept in first-rate order. At that period a young army surgeon of the Tungrian Cohort served on the Wall with such distinction as to earn the monumental stone which is now in the Museum of Newcastle-on-Tyne. The system of Roman roads was well shown in the Ordnance Survey map of Roman Britain which was published a few years ago. This is now succeeded by a map of seventeenth-century England.[1] Attached to the map is an introduction describing the general appearance of the England of those days, by Professor G. M. Trevelyan; and Dr. J. E. Morris has contributed a brief outline of the Civil War.

As Professor Trevelyan points out, the Roman roads had almost entirely disappeared, or had degenerated into mere trackways, and the inland traffic of the country was carried on mostly by saddle and pack-horses. Readers of Pepys will remember that his journeys between London and Huntingdonshire or Cambridge were performed on horseback, and how bitterly he complained of the badness of the ways. The killed and wounded of the Civil War in England were probably fewer than are now the victims of road accidents, but their transport must have been infinitely worse, seeing that only springless carts and pack-horses were available. Indeed, little more than extemporized transport was provided for the wounded by European armies until the Franco-Prussian war.

[1] A Map of Seventeenth-Century England, with Description, Chronological Tables, and a Map of London circa 1660. Scale: 16 miles to one inch. Published by the Ordnance Survey, Southampton.

This map and the accompanying one of London does great credit to the officers of the Ordnance Survey and their enthusiastic voluntary helpers. If not strictly a medical document, it must interest our profession particularly, seeing how many miles of the roads of the country are traversed by them daily.

E. M. L.

THE PHARMACY AND POISONS BILL

ATTITUDE OF THE PHARMACEUTICAL SOCIETY

[FROM A CORRESPONDENT]

The Pharmacy and Poisons Bill, read for the first time in the House of Lords on December 17th, 1930, seeks to amend the existing Acts in many respects. The important changes are, however, comparatively few. The Bill makes membership of the Pharmaceutical Society synonymous with registration as a pharmacist, and imposes an annual registration fee: at present there is no compulsory fee, and membership is voluntary. Chemists' shops are to be registered on payment of an annual fee, the amounts of the personal and shop registration fees being fixed by the society. Provision is made for the appointment by the society of a number of pharmacist inspectors. For disciplinary purposes the Bill creates a statutory committee, to be composed of four persons elected by the council of the society and a chairman having practical legal experience appointed by the Privy Council. This committee has power to remove pharmacists from the register after conviction on a criminal charge or for misconduct, and to remove shops from the register of shops. At present the Privy Council has power of removal but it cannot reinstate, and the power has therefore not been exercised. Another committee created by the Bill is the Poisons Board, an advisory committee to the Home Secretary, which is to consist of fourteen members appointed by various bodies. Five pharmaceutical representatives are to be appointed by the Pharmaceutical Society, the medical representatives being appointed by the General Medical Council and the Royal Colleges of Physicians of London and Edinburgh. A power of appointing four additional representatives, presumably to meet claims to representation not provided for in the Bill, is vested in the Home Secretary. The duties of the Poisons Board are to prepare and submit for the approval of the Home Secretary a Poisons List, which is to take the place of the present Poison Schedule, and to advise him upon the rules to be made under the Act. The Poisons List is to be divided into two parts, the first being concerned with poisons which may be sold only by chemists, and the second with those which may be sold by a class of "listed sellers" created by the Bill. These correspond to the licensed sellers of agricultural poisons, except that a number of poisonous substances—for example, spirit of salt—which are now saleable by any trader, will, under the Bill, become saleable only by these "listed sellers." A further distinction is made in the method of application. At present licensed sellers are required to advertise their application for a licence in local newspapers, and the local authority, before granting a licence, must take into consideration whether the existing facilities for the sale of those poisons are sufficient, and must hear any objections from the police or from existing sellers. This machinery is swept away by the Bill, which requires a local authority to "list" every applicant unless it has some objection to him personally or to his premises. Among the details of the Bill may be mentioned a provision whereby the manufacture of pharmaceutical preparations containing poisons is to be effected under proper supervision, and another requiring that any medicine containing a poison, by whomsoever dispensed, must be labelled with the name and address of the supplier.

THE PHARMACEUTICAL SOCIETY'S AMENDMENTS

The society is not satisfied with the Bill in its present form, and is seeking amendments. Its principal objection is that the Bill makes only a half-hearted attempt to deal with the practice of pharmacy as distinct from

transactions in poisons. Dispensing of medicines containing poisons is dealt with, but not dispensing in general, inseparable though the two things are in practice. The society therefore places at the head of its proposals the requirement that all dispensing in shops should be confined to chemists' shops. In hospitals it proposes that dispensing shall be carried out by, or under the supervision of, a pharmacist, power being given to the Secretary of State to relax those provisions in the case of hospitals where the amount of work to be done, or other consideration, does not warrant them. The dispensing for such institutions must then be carried out by, or under the supervision of, a medical practitioner. Elsewhere than in shops or hospitals (in doctors' surgeries, for example), dispensing is to be done by, or under the supervision of, a medical practitioner. The other provisions of the Bill, relating to the practice of pharmacy, are broadly acceptable to the society. That all pharmacists should be members is a just recognition of the principle that it should not be left to a section of the craft to pay for benefits shared by all. Similarly, the introduction of disciplinary control by means of the Statutory Committee is a needed reform. The registration of shops on payment of a fee, and inspection by statutory inspectors, is not an innovation which pharmacists in business can be expected to welcome, but it has been accepted by the society and endorsed by a meeting of delegates of the society's branches as a preferable alternative to State inspection, and as a recognition of the right of the profession to impose its own control upon its members in the conduct of their professional work.

The creation of a Poisons Board follows closely upon the lines of the society's evidence before the committee responsible for the Bill. There are, however, a number of the proposals in the clauses of the Bill dealing with poisons to which the society will propose amendments. In particular there is no provision limiting the class of poisons which may be sold by unqualified traders, the "listed sellers" of the Bill. The society maintains that the sale of poisons for medical purposes should take place only through the medium of the trained and qualified pharmacist. It therefore proposes to limit the poisons which may be sold by unqualified traders by words which, following the precedent of the present section governing the sale of agricultural and horticultural poisons, will have this effect.

The other provision of the Bill governing the sale of poisons to which the society takes exception will probably be widely criticized—namely, that which requires local authorities to place the name of any applicant upon the list unless they have some objection to him personally or to his place of business. The effect of this clause would seem to be that any reputable trader may, by application, obtain permission to sell any of the poisons included in the second part of the list. At present such poisons as arsenical sheep dips and arsenical weed-killer are in this class, and the result will be to multiply beyond all necessity the number of channels through which these poisons may reach the public. It is certain that the police, the local authorities, and even the manufacturers of the poisons themselves, will not approve of these possibilities of unrestricted sale, with all the chances of accidental, if not criminal, poisoning which they offer. It is therefore less the concern of the Pharmaceutical Society than of the community as a whole that the Bill should be amended to secure that local authorities should have discretion to refuse applications where adequate facilities are already available.

Scotland

New St. Andrews Professor

The University Court of St. Andrews University has appointed Dr. Daniel Fowler Cappell, at present lecturer in pathological histology in the University of Glasgow, to be professor of pathology in the University of St. Andrews, in succession to Professor Sutherland, who retired at the end of the last academical year. He has also been appointed to the associated post of pathologist to the Royal Infirmary, Dundee. After a distinguished career as a student Dr. Cappell graduated M.B., Ch.B. with honours at Glasgow in 1921. Two years later he became assistant to Professor Muir, and assistant pathologist to the Western Infirmary. In 1928 he was appointed lecturer in pathological histology in Glasgow University, and last year graduated M.D. with honours, being awarded a gold medal for his thesis. Dr. Cappell has contributed extensively to the literature of his subject.

Glasgow Western Infirmary

The annual meeting of contributors to the Glasgow Western Infirmary was held on February 6th under the presidency of Lord Provost Kelly, who remarked that the Western Infirmary, which had been established fifty-six years ago, was regarded as one of the best managed and most up-to-date hospitals in the country. Colonel J. A. Roxburgh said that the institution had had a good year, although there was a decrease in the annual general subscriptions and in those from employees. The Western Infirmary had been selected as the radium centre for Glasgow and the South-West of Scotland, and it was hoped that real progress would be made in the treatment of malignant disease. Referring to the Road Traffic Act, 1930, he said that hospitals treating injuries caused by motor accidents were entitled to remuneration up to a maximum of £25 for each case, and that endeavours were being made to arrange with insurance companies that the hospitals would recover with the minimum of trouble what was due to them.

Notification of Mental Defect

A circular has been issued by the Secretary of the Scottish Education Department to education authorities, drawing attention to the provisions of the Education Authorities (Scotland) Mental Deficiency (Notification) Regulations, 1930. It is pointed out that an education authority that has made provision for mentally defective children, either in special schools or classes, or in institutions or under guardianship, must keep under special observation mentally defective children over the age of 15½ years with a view to determining whether any of these children would benefit by being sent to an institution. In such an event the education authority must notify the General Board of Control for Scotland, notice being given before the mentally defective child attains the age of 16 years. Thereafter it is the duty of the town or county council to take over the care and supervision of such children, as was previously done by the parish council. The circular draws attention to the fact that these provisions afford opportunity for much closer co-operation and more frequent consultation than was possible between education authorities and parish councils, and that the question whether a child is capable of receiving benefit from instruction in a special school or class can now be made the subject of joint consideration by the committees responsible for its care. It is suggested that the procedure adopted should enable the committee responsible for the further care of the mentally defective over the age of 16 to keep under observation all mentally defective children passing out of the hands of the education committee, whether or not they are recommended for institutional treatment or guardianship. Copies of the regulations and circular may be obtained from H.M. Stationery Office, George Street, Edinburgh, price 1d. each.

David Elder Infirmary, Govan

A paragraph in the *Journal* of January 3rd (p. 30) referred to an experiment that was about to be made at the David Elder Infirmary, Govan, with a ward for the use of patients who, while unable to pay for treatment in a nursing home, were willing to contribute towards their maintenance in the hospital. This new cubicle ward, which is the gift of Colonel J. A. Roxburgh, LL.D., chairman of the board of managers of the Western Infirmary, was formally opened on January 30th, under the presidency of Sir Henry Mechan. In the course of an address Colonel Roxburgh said that the difficulty was to know exactly what these patients were able to pay and what kind of accommodation was necessary. While some other institutions in Glasgow were providing special wards for paying patients, he had wondered if it was not possible to treat these persons along with the ordinary patients, who already had the benefit of the best available medical, surgical, and nursing skill, and the advantage of the most up-to-date equipment. If they were asked to pay anything, he thought they must have a measure of privacy, which, after all, differentiated the nursing home from the hospital ward. The present experiment was being made in the hope that, if it proved successful, other wards of the same kind would be added. No fixed sum was being charged at present, but all patients were expected to pay something. They would receive the same surgical and nursing attention as was given to the other patients in the Infirmary. Sir Henry Mechan referred to the generosity of Colonel Roxburgh, who, he said, had defrayed the whole cost of building and equipping the new wing. The extension is divided by partitions and curtains into seven cubicles, each of which has a bed, a locker, a chair, and a wireless receiving apparatus. Cubicles can be made entirely self-contained, so that patients may have complete privacy. One of the features of the building, which has a southern aspect, is a veranda in front large enough to accommodate beds.

The Peking Skull

A lecture on the Peking skull was delivered by Professor G. Elliot Smith in the anatomy department of Edinburgh University on January 30th, under the auspices of the William Ramsay Henderson Trust, which exists for the purpose of advancing the knowledge of brain physiology. Professor Elliot Smith described the fossil remains of early Pleistocene man which he examined in Peking as the most significant and illuminating example of early man that had yet been discovered. His earlier lecture on the same subject was summarized in the *British Medical Journal* of January 24th.

England and Wales

Dr. Griffith Evans of Bangor

The freedom of the city of Bangor has been conferred on Dr. Griffith Evans, who is in his ninety-sixth year and has been a member of the British Medical Association since 1874. Before graduating M.D. of McGill University, Montreal, Dr. Evans was a veterinary surgeon in the Army. It may be recalled that he discovered in India that surra, a disease of horses, mules, camels, and cattle, was caused by a trypanosome to which the name *Trypanosoma evansi* was subsequently given. He was awarded the Mary Kingsley medal of the Liverpool School of Tropical Medicine for devotion to science. At a public ceremony in Bangor Dr. Griffith Evans was represented by his daughter, and the mayor afterwards visited Dr. Evans at his bedside and handed him a casket containing the freedom.

The Rise of Tropical Medicine

A public lecture on "The dawn of tropical medicine," being an account of the life and work of Sir Patrick Manson, was delivered by Dr. Philip Manson-Bahr at the opening of the ninetieth course of study at the London School of Hygiene and Tropical Medicine on February 3rd. The chair was taken by Sir Harry Goschen, who paid a high tribute to the late Sir Andrew Balfour, one of Manson's earliest students, a man of sterling character, simplicity, and directness of purpose, who worked with consuming energy and high sense of duty for the task to which he had put his hand when accepting the post of director of the school. Dr. Manson-Bahr, in the course of his lecture, said that Patrick Manson, to whom the London School of Hygiene and Tropical Medicine owed its inception, was one of the most original and outstanding medical personalities of the last century. Not only did he himself make many lasting discoveries in the field of medicine; but he laid the foundations of the science of tropical medicine, and to a great extent revolutionized the health conditions in tropical countries. Small wonder, then, that his name was held in sacred remembrance and that he had joined that glorious company in which figured Pasteur, Lister, and Koch. It was in 1875 that Manson first saw the microscopic embryo filaria in the blood of the local Chinese, and it was in the elucidation of the life-history of this parasite that he first achieved fame. After a busy interlude of seven years in Hong-Kong he returned to England and continued a study of the parasites of the blood, in which he made many striking discoveries. In 1892 he began to study malaria seriously, and, after many ingenious observations, was able to deduce the probable life-history of the malaria parasite from what he had already ascertained to be the case in the filaria. In 1894 he formulated his mosquito-malaria hypothesis and became associated with Ronald Ross, and this collaboration resulted in verification of the complete cycle of the malaria parasite in the anopheles mosquito in 1898. In 1897 Manson was appointed medical adviser to the Colonial Office, and became intimately associated with Joseph Chamberlain in schemes for the betterment of health conditions in the Colonies. The first outcome of this was the foundation in 1899 of the London School of Tropical Medicine. In 1920 the school moved to Endsleigh Gardens, where it was housed with the Hospital for Tropical Diseases. Nine years later it was transferred to its present magnificent home, and the hospital had been repaired, enlarged, and reorganized to meet the new conditions. All this and more also did Manson accomplish, so that out of his life and example there had arisen the Mansonian tradition which infused all workers in the school.

The Board of Control

Pursuant to the provisions of Section 11 of the Mental Treatment Act, 1930, the Board of Control, with the approval of the Minister of Health, has appointed the following to be Commissioners: A. E. Evans, M.B., D.P.H., S. E. Gill, M.D., D.P.H., E. O. Lewis, D.Sc., L.R.C.P., J. W. W. Adamson, M.D., Surgeon Rear-Admiral J. F. Hall, C.M.G., K.H.S., R.N.(ret.), Surgeon Rear-Admiral E. T. Meagher, R.N.(ret.), at present Medical Inspectors; and Mr. C. F. Penton, barrister-at-law, Miss I. M. C. Duncan, B.A., LL.B., barrister-at-law, Surgeon Captain H. C. Devas, R.N.(ret.), Miss I. G. H. Wilson, M.D., D.P.M., and Miss R. Darwin (part-time).

Epsom College

We learn that the building of the school sanatorium at Epsom College is progressing apace, and that it is likely to be completed in July. This will enable the existing sanatorium to be transformed into an additional

boarding house by next September term. Room will thus be available for another twenty-five boarders, which will lessen by that amount, at any rate, the number of applications for residence as boarders that have had to be declined recently. With this addition the number of boys at the college will be 450.

Correspondence

X-RAY THERAPY IN MALIGNANT DISEASE OF THE LUNG

SIR,—In your issue of January 24th Mr. Tudor Edwards states that deep *x*-ray therapy "has proved very disappointing for primary malignant lung tumours, and I have yet to see a patient who has benefited thereby." This remarkable statement cannot be allowed to pass without comment. One can only conclude that Mr. Edwards's experience of *x*-ray therapy in this condition is either very limited or very unfortunate. I for one have had cases in which there has been undoubted material benefit as regards alleviation of symptoms and prolongation of life, and other radiologists have had similar experience. In Germany, where there is very little radium, *x*-ray therapy is being carried on with considerable success on a large scale.

Mr. Edwards goes on to say: "Unless other methods fail I am disinclined to recommend this treatment to my patients at the present time." Personally, I should have thought that in malignant disease of the lung the opinion of a surgeon should be limited to the question of surgical intervention, and that the advisability of *x*-ray therapy might more properly be left to the physician and radiologist. A surgeon recently stated in your columns in another connexion that "*x*-ray therapy had been disappointing to surgeons." Why "to surgeons"? Have the results of surgery invariably been gratifying to radiologists? Radiologists are not in the habit of criticizing surgery, and they expect the same of surgeons with regard to *x*-ray therapy. If surgeons must go outside their proper sphere their opinions should at least be restrained and well informed.

While happily the great majority of surgeons do not take the view of which I complain, recent contributions to the *Journal* have made it clear that a certain number of surgeons adopt towards *x*-ray therapy a contemptuous and patronizing attitude which sometimes amounts to actual hostility, and it is remarkable that these are the very men whose enthusiasm for radium, provided that this means "surgery of access," knows no bounds. Mr. Edwards sweeps aside all forms of radium and *x*-ray therapy except those in which the surgeon participates. This attitude is, to say the least, unbalanced, and shows an imperfect appreciation of the nature of electromagnetic radiation.

Radiologists will join with others in congratulating Mr. Edwards on his success in what must be an extremely difficult branch of surgery. In view of the technical difficulties involved, the surprising thing, as Dr. Johnson said of the dog walking on its hind legs, is that he can do it at all. Radiologists will be the first to admit that no amount of radiotherapy, whether in the form of radium or *x* rays, can be as effective as the removal of a tumour. But after all, Mr. Edwards numbers his cases in which he has had any measure of success on the fingers of one hand, out of a total of 118. Is he therefore in a position to throw stones at others, to condemn with unbounded confidence a form of treatment with which he is not concerned and with which he has clearly very little acquaintance?

The way is long and arduous. Nothing is more necessary at the present day than that those who employ different methods should show towards one another, not an attitude of narrow parochialism, but a spirit of generous co-operation, understanding, and encouragement.—I am, etc.,

Cambridge, Feb. 2nd. FF. ROBERTS.

SEPTICAEMIA FROM MINOR WOUNDS

SIR,—Although no mention is made of the result of a bacteriological examination, there can be little doubt that the two tragic cases reported in your issue of February 7th (p. 242) by Mr. Ian Fraser were due to *Streptococcus pyogenes*—a diagnosis with which he evidently agrees, because he employed antistreptococcus serum. As Mr. Fraser invites suggestions, I am writing to propose that in the next case he should try sensitized vaccine of *Strep. pyogenes*, and that he should be sure to give it in sufficient dose.

From the bacteriological point of view, cases of acute infection by *Strep. pyogenes* are perhaps the most important and tragic of all those admitted to a general hospital. During the five years immediately preceding the war I had the privilege of acting in close collaboration with the junior staff of St. Bartholomew's in investigating such cases, and as a result formed the opinion that these patients can be classified roughly into three groups according to the degree of their resistance to the streptococcus. Group I are instances of fulminating septicaemia, and rapidly succumb whatever the treatment adopted. Group II appear to be almost, if not quite, as ill as Group I when admitted, but a large proportion recover, mainly, no doubt, as the result of treatment. Group III, on the other hand, have a much stronger natural resistance. The infection remains localized, and these patients can recover without any special treatment at all.

At the time these cases were being observed I was under the impression that there were in all probability several different kinds of *Strep. pyogenes* concerned in them. This view I no longer hold, because, on resumption of hospital work after the war, a special serological survey of these haemolytic streptococci was undertaken on behalf of the Medical Research Council. The result was reported in the *British Medical Journal* of April 30th, 1921. Out of 114 examples of haemolytic streptococci collected from hospital cases of all sorts, and submitted to scrutiny by the absorption of agglutinin test, no fewer than 107 conformed to one and the same serological type. The haemolytic streptococci from cases of puerperal sepsis appeared to be identical with those from cases of ordinary sepsis. The name *Strep. pyogenes*, therefore, would seem to be a just one for this micro-organism.

With regard to specific treatment, it is probable on general grounds that this will be successful in proportion as it approximates to the natural process of recovery, and here, unfortunately, there are still considerable gaps in our knowledge. The opinion formed by me in assisting to deal with the cases referred to was that neither vaccine nor any serum then available could be relied upon *per se* materially to promote recovery in really severe cases. The defects of serum and vaccine, however, seemed to be remedied to a considerable extent by combining the essential features of both in the form of sensitized vaccine after the manner suggested by Besredka. Such a vaccine can be prepared without much trouble in the following way. Surface cultures of *Strep. pyogenes* are made on half a dozen agar plates, the medium being enriched with serum before being poured. The growth on these plates after one day at 37° C. is washed off in saline, and heated for thirty minutes to 65° C. The number of cocci per cubic centimetre of the suspension is then determined by a

simple turbidity test, and an amount of it containing approximately 25,000 million cocci is diluted to 5 c.cm. with saline and put into a centrifugé tube, to which 5 c.cm. of antistreptococcus serum is added, and the mixture well shaken. It is essential that the serum contains agglutinin for the streptococcus, and the stronger it is in this antibody the better. After standing overnight, either at room temperature or at 37° C., the cocci should all be agglutinated and collected in flocculi at the foot of the tube, the fluid above being clear. The tube is then centrifuged for five minutes, after which the fluid is removed and replaced by saline; the deposit is shaken up in this, and again centrifuged out. The saline washing is then removed, and the sensitized cocci once again taken up in fresh saline containing 0.5 per cent. of phenol, and transferred to one or more vaccine bottles with rubber covers.

After a sterility test, the sensitized vaccine prepared in this way is given subcutaneously. The doses administered have been 100 million, 250 million, 500 million, 1,000 million, 2,000 million, 4,000 million, etc., at intervals of twenty-four hours, according to the progress of the case. Provided that it has been properly sensitized, the vaccine produces no reaction. The effective dose is found by observing the general condition of the patient and the temperature chart. In a recent case a patient suffering from severe infection by *Strep. pyogenes* had been given considerable amounts of serum, including the antitoxic serum, without benefit. Improvement in that instance began when the dose of sensitized vaccine reached 4,000 million, and ultimately he made a good recovery. It is important in severe cases that the treatment should be continued for a few days after improvement sets in.—I am, etc.,

London, W.C.1, Feb. 7th. M. H. GORDON.

THE PROBLEM OF ANIRIDIA

SIR,—Cases of aniridia are so rare as to make the following worth placing on record.

A patient, aged 8 months, admitted as a case of gastro-enteritis, was found to have aniridia. The condition of the infant was pitiable, even the subdued light of the ward causing acute discomfort. The pink retinal reflex obvious at the first glance made one think the child was an albino. The mother also had the defect, and reported that out of her eight children, four, two boys and two girls, had the same condition. Neither her father nor mother, nor any other member of either family, was known to be affected. The mother can just see shapes and distinguish colours. The sequence of affected children was first, fourth, sixth, and eighth.

If, as is suggested, aniridia is a recessive Mendelian factor, these cases would meet the requirements of the theory on the supposition that the father is heterozygous. The mother's explanation, however, is that her own defect is in answer to her mother's prayer that her husband should have a great shock, to lead him to bring his conduct into line with her requirements. Thus the mother's suggestion is that the defect has arisen *per saltum* in herself.

The condition, especially as it concerns this family, is of interest not only on account of the hopeless outlook for the patients themselves, but also with regard to the economic importance of the defect, none of the sufferers being capable of earning a livelihood in the ordinary way, and therefore becoming burdens on the community all their lives. The boys may become miners, but what are the girls to do? Yet more important still is the future of the eight children as regards progeny—a matter on which there is at present much loose thinking. The courses open appear to be: (*a*) Our present method —to leave things to take their own course—which is silly. (*b*) To allow them to marry, but advise them to have no children—which is as idealistic as futile. (*c*) To allow marriage, but provide contraceptive literature and the requisite appliances, as suggested by many societies and clinics—which proves a failure. (*d*) To segregate for life —so deliciously bureaucratic. (*e*) To sterilize them, and allow them to marry or not at will—which is so simple and effective as to be anathema to most.

Is the sufferer to have any choice in this matter? At present he can please himself which he chooses, except the last. Surely it is time views on such matters should cease to be so nebulous and the products of prejudice rather than reason, and that the medical profession should give a definite lead.—I am, etc.,

Manchester, Feb. 4th. J. D'EWART.

TREATMENT OF VARICOSE ULCERATION

SIR,—Undeterred by Mr. Davies's rebuke in his letter in your issue of January 31st, I would like to repeat that the method which he proclaims to be entirely new and original is indeed on exactly the same principle as that of the firm bandaging recommended from time to time by various writers during the last two hundred and fifty years. Mr. Davies is evidently unfamiliar with the writings of those who have formerly advocated treatment upon this principle of counteracting the effects of gravitation by means of equable pressure, and of thus reducing the oedema and curing the ulcer while the patient is still walking about.

So early as 1676 Richard Wiseman, Sergeant Chirurgeon to King Charles the Second, in his *Chirurgical Treatises* records cases of varicose ulcer which were cured by first reducing the swelling by having the leg "rowled up with a Compress and Bandage from Foot to Gartering," and then continuing the treatment with a "laced-stocking." Michael Underwood, M.D., in a *Treatise on Ulcers of the Leg* (1783), laments the fact that "compression by firm bandaging is as a general practice so much out of fashion, though once in great esteem with eminent surgeons, and particularly Wiseman, whose contrivance the laced-stocking seems to have been." He pleads for the treatment of these ulcers without rest and confinement, but with tight bandaging. Thomas Whately, surgeon, in *Practical observations on the cure of Wounds and Ulcers of the Legs, without rest* (1799), a work of 352 pages, with records of 167 cases cured, refers to the method of Wiseman and of Underwood, and regrets that the system has been brought into discredit because the principle of general and equable pressure has not been properly carried out. Again and again he insists upon the necessity for firm pressure, and that the bandage cannot perform its designed office unless it be so applied as to make the necessary pressure from knee to toes: "In almost all these cases, before the cure is attempted, the leg is more or less enlarged by swelling; and as this swelling is entirely removed by compression it readily allows the skin to approximate on the healing of the ulcer." Thomas Hunt, to whose small book I referred in my letter of December 27th, repeats the same tale: treatment to be ambulatory, effect of gravitation to be overcome by firm bandaging, failures due to inadequate application of bandage.

I have no desire to discredit the Dickson Wright method, nor do I doubt the good results (54 cases; 31 cured, I improved, 22 still under treatment="100 per cent. results"!), but I maintain that equally good results can be obtained with the simple flannel bandage properly applied. It seems to me that the older method carries out the principle of firm support or pressure in an even more scientific manner, because by the daily reapplication

of the bandage the pressure is repeatedly adjusted to the gradual shrinkage of the swollen leg, whereas however tightly the elastoplast bandage may be applied in the first instance, since it remains on for a week, such continually increasing pressure cannot be efficiently maintained.—I am, etc.,

London, W.1, Feb. 5th. H. G. ADAMSON.

THE ENIGMA OF THE CHILBLAIN

SIR,—The article on this subject by Dr. Rupert Hallam in your issue of February 7th contains many data of scientific interest. I venture, however, to challenge his third sentence, which reads: "It is improbable that efficient means of prevention will be found until more is known of the etiology and pathology of the condition." If Dr. Hallam will visit the Continent as a layman, he will find that in climatic and other etiological conditions varying in but a minor degree from those existent in England, the chilblain is a rarity. Among well-to-do women in France, Switzerland, Germany, and Holland, chilblains are practically unknown, and English ladies accustomed to suffer every winter from chilblains in this country are surprised to discover, if they have occasion to pass a winter abroad, that they escape from this troublesome disorder.

I suggest to Dr. Hallam that however important inborn factors governing nutrition, circulation, and metabolism may be, the all-important factor in the production of chilblains is the shibboleth of the virtue of cold bedrooms which has come to us from our Victorian forebears. To come down to breakfast with frozen hands and feet, and to thaw them before a glowing fire, or to enter an arctic bed and place the numbed feet against a burning hot-water bottle, are sure ways of contracting this complaint.

Trench foot, which caused incapacity in thousands of soldiers during the late war, was not a matter of metabolism, latent tuberculosis, or inherent vasomotor defect; it was preventable by discipline and common sense. Chilblains are preventable by common sense and discipline of a less exacting nature than that which ancestral tradition still inflicts upon us.—I am, etc.,

London, W.1, Feb. 7th. T. IZOD BENNETT.

GLYCERIN AS A SURGICAL DRESSING

SIR,—I should like to add to the recent letters in the *Journal* something which may throw further light on the value of glycerin as an antiseptic. In 1914 (*Lancet*, December 5th) I wrote a short note on the use of glycerin in bromidrosis, showing how bacterial growth was controlled and fetor prevented. In 1919 (*Journal of Laryngology*, xxxiv, 9), in conjunction with Mr. C. H. Hayton, I described how the treatment was extended to ozoena by local application of glycerin and glucose, and proved its effectiveness. In an extended investigation of the rationale of this method of treatment we came to the conclusion that the fetor arose as the result of tryptic fermentation, and it was characteristically produced in pure cultures of Perez bacillus in broth. On the addition of glycerin and glucose to broth cultures of *Staphylococcus albus* and Perez bacillus, although the bacillus grew freely, the fetor did not appear, and the medium became acid in reaction. The presumption was that the acid reaction had inhibited the tryptic bacterial digestion, and had prevented the formation of end-products of the skatol and indol class. Further, it is probable that the products of bacterial growth on a medium containing a fermentable substance of the type of sugar or glycerin are, in general, less toxic than those grown on a purely protein one (no doubt the resulting acidity has something to do with this), though I would not like to assert this in every case. Arguing on these postulates, I was able to get the casualty house-surgeons at the Prince of Wales's Hospital (Dr. J. Young in 1919 and Dr. M. Y. Paget in 1924) to treat a series of recent wounds with a mixture of 10 per cent. glycerin, 60 per cent. commercial liquid glucose, and 30 per cent. water. The wounds were taken as they came to the casualty department, and without cleaning up, except with soap and water, the mixture was put straight on, covered with lint and mackintosh, bound up, and usually left for three days, after which a dry dressing with boric acid powder was substituted.

I do not remember an acute septic condition resulting in any of these cases until we ambitiously tried the method in a severe complicated fracture with mangling of the forearm and ingrained dirt; this case certainly did go septic, but cleared up in due course. A marked feature of many of the wounds treated in this way was the one noted by Dr. Kyle in his earlier cases. For some days the tissues over an area of an inch or more around the wound remained puffy and oedematous, but not red or inflamed. The wounds were by no means always sterile; cultures showed that they were healing in some cases in the presence of a considerable bacterial flora, mostly saprophytic, but often *Staph. aureus* and *albus* were present, and occasionally streptococci. The bulk of these cases were wounds and lacerations of the hand, and the treatment seemed best adapted to relatively superficial lesions with loss of tissue and ingrained dirt. In all, I should think upwards of 100 cases were treated in this manner. Although all cases did not heal by first intention we were satisfied that there was far less real sepsis than usually results when vigorous antiseptic measures are adopted. The resultant scars were soft and supple.

One would not recommend this as a standard method of treatment for all wounds, since many other factors than antisepsis have to be considered in dealing with various types of injury. I merely put it on record to show the antiseptic power of these substances used as a dressing on dirty wounds. This power may be attributed probably both to the hygroscopic properties of the glycerin and glucose, and to the fact that these substances in solution in the tissue juices can follow the bacteria into the tissues, probably diminishing the toxic effects of their growth. We tried this method in a number of old ulcers and suppurating wounds, but without the least effect; but we did not treat active boils or carbuncles in the way described by Dr. Kyle.—I am, etc.,

London, W.1, Jan. 29th. T. H. C. BENIANS.

TREATMENT OF ETHMOIDITIS

SIR,—I entirely agree with the remarks of Mr. J. B. Horgan in his letter (January 31st, p. 200) regarding the treatment of nasal sinusitis. His fifth point is very important—namely, to leave the middle turbinal till the end of the operation and then to remove, if any, only as much as is advisable by a graduated turbinectomy, cutting through, with a snare, the part severed from the line of attachment, without any wrenching. When I use a curette to exenterate the ethmoid, like Mr. Horgan I also work from behind forwards and downwards, although I have never performed his operation through the antrum.

The above points were strongly impressed on my mind by the late W. S. Syme. Although Syme was regarded as one of the foremost advocates of radical operative procedure in connexion with nasal sinusitis, he recognized that the middle turbinal should be treated with the greatest respect in these cases. Personally I have found

that any cases giving rise to anxiety thirty-six hours after the operation in the matter of severe headaches, epistaxis, rise of temperature, etc., have nearly always been associated with removal in part, or in whole, of the middle turbinal. For this reason I also do not perform Sluder's operation.—I am, etc.,

Blackpool, Feb. 5th. W. BARRIE BROWNLIE.

SIR,—In your issue of January 24th (p. 158), Mr. O'Malley refers to my paper, "A safe method of dealing with ethmoiditis," and I hasten to explain that I regard the whole method as essential—namely, (1) a radiographic examination is made; (2) the frontal sinus is drained if shown to be infected; (3) as a routine operation the middle turbinal is removed, and the maxillary antra and sphenoidal sinuses, the main inferior cisterns of the ethmoidal system, are permanently drained. Only as a secondary operation under local anaesthesia should other polypi be removed and closed cells opened if causing trouble. I believe that removal of the ethmoid mass in bulk, as practised in Sluder's operation, has caused many fatalities, has often failed to open closed cells, or has resulted in a dry nose.

I do not think that Mr. Horgan's remarks (*Journal*, January 31st, p. 200) have helped me much, though I have read his longer paper on the subject. In summarizing the whole story he omits radiography, which I cannot but think would help him in the diagnosis and recognition of the presence of a frontal sinus. Again, he objects to the removal of a middle terminal with Luc's forceps as encroaching upon the dangerous area, but in paragraph 7 allows this to be exceptionally carried out at the end of the operation with scissors and snare. Yet in ethmoiditis the obstruction of which the patient complains is due to polypoid masses of degenerated middle turbinal, and till these are removed the patient cannot breathe through the nose, nor can the surgeon obtain a view of the interior. Surely the dangerous area lies above the attachment of the middle turbinal. In paragraph 3 he insists on an *à froid* condition of the sinus prior to operation. It would certainly be dangerous to leave an acute frontal sinus undrained, though wise to do nothing more than secure drainage.—I am, etc.,

London, W.1, Feb. 7th. E. A. PETERS.

PREGNANCY FOLLOWING IRRADIATION

SIR,—In the *British Medical Journal* of July 26th, 1930 (p. 156), under the heading "Radium treatment of menorrhagia," the records of University College Hospital are quoted regarding the health of children born subsequent to such treatment. The article continues:

"As far as is known, only two of the patients have become pregnant after radium treatment; one gave birth at full term to a male child with double inguinal hernia, the other miscarried. These experiences and evidence derived from animal experiment suggest that the children of parents thus irradiated will be physically and mentally abnormal, and there are serious grounds for the view that young patients should not be treated by irradiation unless they are given doses large enough to produce sterility."

Recently the Gynecean Hospital Institute of Gynecologic Research of the University of Pennsylvania undertook an investigation dealing with the health of children born following maternal pelvic radium or roentgen irradiation. This investigation led to the following conclusions:

1. That irradiation of a growing human embryo is extremely likely to result in the birth of a defective child.

2. That treatment prior to conception will have no influence whatever upon the development or later health of any subsequent child, conceived following irradiation.

In order to substantiate these two statements, in so far as that may be possible, I am enclosing a group of reprints dealing with the problem, published by the Gynecean Hospital Institute.—I am, etc.,

DOUGLAS P. MURPHY, M.D., F.A.C.S.

University of Pennsylvania, Jan. 24th.

*** The reprints forwarded by Dr. Murphy may be read at the Library of the British Medical Association.

CATARACT OPERATION IN EXTREME OLD AGE

SIR,—Some years ago, in India, an extremely old-looking Sikh came to me with cataract. When I asked his age he said it was 100 years. Knowing how utterly unreliable statements about age so often are in certain patients in India, and of the tendency in some parts for old men to exaggerate their years, we went closely into the question as to how he knew his age. He told us that he had fought against the British in the Sikh wars, and gave his age at the time. We were satisfied that it tallied with what he claimed to be. I had no doubt as to his having been a soldier. Indians usually age more rapidly than Europeans, but the Sikhs are a strong race. Having read about Colonel Elliot's old lady of 96 (*Journal*, January 24th, p. 132) I am confirmed in my opinion that this man was a centenarian. I may add that his age was given during the ordinary routine questioning, and he did not seem to be particularly proud of it; he was a simple villager, and I could see no reason for his wishing to deceive me.

I extracted one of his cataracts in the capsule by Smith's method. The cornea was one of the thinnest I have ever incised, but the course of the case was uneventful. I should be very interested to hear if any other operator in North India has come across a centenarian in his cataract work.—I am, etc.,

A. E. J. LISTER, M.B., B.S.,

Clifton, Bristol, Feb. 7th. F.R.C.S.

THE UNIVERSITY FRANCHISE

SIR,—The Representation of the People (No. 2) Bill came before the House of Commons yesterday, with its clause abolishing University Franchise. The introducer of the Bill, the Home Secretary, in his comments upon this part of the Bill, clearly showed the real motive of the clause. He said that the university electorate is so small that twelve members were returned by some 120,000 voters, and he went on to say that "it will not do in these days when, say, we have an average constituency of 60,000 electors for one member, to give a round dozen of members, in the main Tory members, to 120,000 electors." It is thus nakedly stated by the introducer of the Bill that the motive in this clause is to remove from Parliament certain members because they are mainly opposed to the Government in power. This action was foreseen by Lecky thirty years ago, when he wrote of university representation:

"According to any sane theory of representation no form of representation could be more wise. Its abolition would not have very extensive consequences, but it would at least expel from Parliament a small class of members who represent in an eminent degree intelligence and knowledge diffused throughout the country; who, from the manner of their election, are almost certain to be men of political purity and independent character, and who, for that very reason, are especially obnoxious to the more unscrupulous type of demagogue. Their expulsion would be a considerable party advantage to one faction in the State, and it is therefore likely to be steadily pursued."

The precedent thus made might have serious consequences if the principle comes to be adopted that whenever a party in power finds a class of members obnoxious

to itself it can, by exercise of its parliamentary majority, simply expel those members.

The present attack upon the university representation is all the more remarkable when one reflects that as recently as 1918, in the framing of the Franchise Act of that year, university representation, far from being abolished, was actually increased as the result of a long, careful, and above all disinterested consideration of the whole question of the franchise. The Act of 1918 carried out, for the most part faithfully, and in regard to university franchise with complete fidelity, the recommendations of the Speaker's Conference, which all through 1917 had gone into the whole question. That conference was composed of representative members of all parties. It issued an agreed report which was a compromise between contending interests offered to and accepted by the House of Commons as such. In the second reading debate Sir Herbert Samuel, speaking for the Liberal members of that conference, of which he had been one, very clearly expressed the position (Hansard, volume 93, 1917). He said:

"The retention of University Representation is to my mind most regrettable. . . . But this is a compromise Bill, and however much some of us may dislike some of these provisions, we accept them frankly and without dispute or controversy, because we know that others who hold opposite views have also given up points to which they attached importance, and it is only by a general surrender here and there of things which each of us regard as not necessarily essential that it is possible to secure that general agreement by which alone a measure of this character can be carried."

Now the Liberal party, only twelve years after this solemn agreement was reached, treats it as a "scrap of paper." Of course there is no intention or effort to restore those provisions alluded to by Sir Herbert Samuel which other parties to the agreement gave up in return for the retention of university representation. There could be no more flagrant breach of the immemorial instinct of Englishmen to "play the game" than is offered by this cynical disavowal of a pact only twelve years old.

Public opinion, I think, is likely to take notice of these circumstances, and the medical profession is peculiarly able to influence public opinion. The Bill will doubtless pass its second reading to-night, in accordance with the bargain which has been made between the Liberal and Labour benches, but there is clearly considerable dissatisfaction and some dismay among Labour members at the explosion of public opinion that has taken place upon this particular matter, and there is some prospect that this clause may be rejected in committee. Happily the Bill will go before a committee of the whole House, and will thus be fought out upon the floor of the Chamber, and not in the fastnesses of rooms "upstairs." In these circumstances public opinion can make itself felt throughout the committee stage, and it is with the object of enlisting the support of the *British Medical Journal* and of inviting it to take its share in moulding that opinion that I write this letter.—I am, etc.,

House of Commons, Feb. 3rd. E. GRAHAM-LITTLE.

THE LONDON CLINIC AND NURSING HOME

SIR,—The building of the London Clinic is now nearing completion, and the Executive Committee of the Medical Advisory Board consider that the time has come to explain its objects and ideals more fully, and to give some details of the means by which it is hoped that they may be achieved.

It has long been realized, both by the medical profession and by the lay public, that the modern developments of medicine necessitate wider facilities for the investigation and treatment of disease than are at present available for the general public. There is probably no city in the world which presents such a contrast in the provision it makes for illness as does the city of London. On the one hand, there are the voluntary hospitals, unrivalled as monuments of charity, where the poor have at their absolute disposal every resource that modern medicine can provide or surgery devise. On the other hand, those whose circumstances or whose pride remove them from the hospital class have often to be satisfied with makeshift accommodation, and are excluded from the resources in equipment and co-ordination which are the foundation of the work of our hospitals.

Modern specialist treatment can be carried out only in a building specially adapted for the investigation and treatment of disease, organized on modern lines, and provided with adequate laboratories and *x*-ray equipment. The need for such a building containing rooms to suit all classes of paying patients is so obvious that one would have thought little difficulty would be experienced in finding the money for its erection. Yet this has taken twelve years of difficult negotiation to achieve. Faced with the dilemma that, on the one hand, there is a strong feeling against the financing of nursing homes by medical men, whilst on the other no financial group was prepared to take a financial risk which medical men refused to share, a solution agreeable to both parties was at last reached. A company was formed to put up a building consisting of a nursing home, for the finance of which the company would be responsible, and a number of consulting rooms, the lease of which the medical men might purchase without any breach of medical ethics. This arrangement assured the company of satisfactory medical support without involving medical men in financial responsibility for their affairs.

The building, which is rapidly approaching completion, is situated on the south side of the Marylebone Road, bounded on the west by Devonshire Place and on the east by Harley Street. Special care has been taken to protect the patients from noise and vibration. The steel uprights which support the building are embedded in a system of padding which ensures a complete absence of all vibration. The patients' rooms face not on the Marylebone Road, but on the south, south-east, and south-west frontages, where they enjoy a wide outlook and are entirely protected from noise. The building is so high that many of the rooms enjoy a view extending across London to the hills of Kent.

The building has been designed with the utmost care, and in constant consultation with expert medical opinion. In order to obtain the very latest information on modern hospital equipment and organization, a committee of the directors of the company and the members of the Medical Group visited all the most modern hospitals in Sweden, Denmark, Holland, and Paris, as well as others in France, Germany, and America, and we are convinced that this clinic will set an entirely new standard in design and equipment. A wide range of accommodation between small single rooms and private suites will meet the varying requirements of patients, but in every instance the standard of comfort will be the highest attainable, and special attention has been paid to those small amenities which mean so much when one is ill. The kitchens will be on the most modern lines, and in view of its increasing medical importance a special diet kitchen under expert control has been installed.

An outstanding feature is the provision made for maternity cases and for children. For the former a separate floor has been specially equipped, with arrangements which ensure absolute quiet and privacy, and a special nursing staff will be reserved exclusively for these

patients. The children will be accommodated in a separate wing, so arranged that each child can, if necessary, be accompanied by its own family nurse, while a large solarium, opening directly on the south side of this wing, will give every possible opportunity for fresh air and sunshine.

As regards the staffing of the hospital, two features will add greatly to the comfort of the patient: the nursing staff will be sufficiently large to supply special nurses—usually a costly item—at a very low charge; and there will be two resident medical officers who can be called upon at any moment of emergency. In regard to the latter, it must be clearly understood that these resident medical officers will in no way usurp the authority of the patient's own medical adviser. It is an essential part of our conception that the patient should still remain in contact with his regular doctor, for we consider this of the utmost importance for the continuity of treatment. The building will thus be a large nursing home open to the medical profession of the whole country, equipped and staffed with all the resources of a modern hospital.

In addition, it is proposed to develop within the group of medical men who occupy the consulting rooms a plan of combined work, so that patients of moderate means may be saved the multiple consultations, involving so much expenditure of time and money, which often make the elucidation of their malady such a costly process. Such service of mutual assistance between the members of the staff is universal in our voluntary hospitals, and there is no single feature of their organization which is of greater value to the patient. The development of such a service for those who are just outside the hospital clientele is by no means an easy matter, and will demand very careful consideration. We have no doubt, however, of the necessity for such a service, and its provision will be one of our earliest objects. By such a service, backed by rooms at the lowest charge which is economically possible, we shall effectively bridge the present gulf between the poor and the wealthy. We would, however, reiterate that this service, in common with all the other services of the clinic, is available to patients solely through their medical advisers. A wide experience has convinced us that to make use of specialists' services except in a consultative capacity is a definite disadvantage to the patient, whose interests are best served by the closest possible co-operation between those who have charge of his health.

This is the first real effort in this country to extend the advantages of an organized specialist service to those who are excluded from the services of charity. It will provide suites of rooms offering a convenience and a comfort never before attempted, whilst more modest accommodation will be available at the lowest rates compatible with efficient treatment and service. The dreams of the group of medical men who are responsible for its initiation have only been brought to fruition by years of laborious effort. It is their earnest desire that this building should be freely open to the whole of their medical brethren, and that it should bring within the reach of patients of every class advantages which have not hitherto been generally available.—We are, etc.,

Obituary

SIR A. GARROD THOMAS, LL.D., M.D.

Consulting Physician, Royal Gwent Hospital, Newport

Sir A. Garrod Thomas, whose death on January 30th we recorded briefly last week, was born in Cardiganshire on October 5th, 1853. He received his early education at Milford Haven and spoke nothing but Welsh until he reached his teens. After studying medicine at the University of Edinburgh, and subsequently in Berlin and Vienna, he graduated M.B., C.M.Ed. in 1876, and after taking the M.R.C.S.Eng. diploma proceeded to the M.D. two years later. While at Edinburgh he was a pupil of Lord Lister, whose work made an ineffaceable impression on his outlook. On becoming physician to the old Newport Infirmary in 1895, he realized the need for a better building, and he and his wife took a prominent part in the campaign for erecting and equipping the Royal Gwent Hospital; they started the fund by contributing £5,000. For many years he served on the honorary medical staff, and in 1904 became chairman of the board. On retirement from the active staff he was appointed consulting physician. To mark the completion of twenty-five years as chairman of the hospital he was presented with a bronze bust of himself, which is to remain in the hospital in perpetuity; a replica of the bust was installed in the Newport Museum last December.

Sir Garrod Thomas took great interest in local affairs, and his public spirit and generosity were recognized throughout South Wales. For three years he was a member of the Newport School Board, and served for eight years as a member of the town council. He was a justice of the peace for the counties of Cardiganshire and Monmouthshire and for the county borough of Newport. In 1900–1 he held office as high sheriff for Cardiganshire, and was appointed by the late Duke of Beaufort a deputy lieutenant for Monmouthshire. The honour of knighthood was conferred upon him in 1912. On the occasion of the Annual Meeting of the British Medical Association in Swansea in 1903 he was vice-president of the Section of Diseases of Children, and he had been president of the South Wales and Monmouthshire Branch. Sir Garrod Thomas was a liberal in politics, and was elected to the House of Commons as member for South Monmouthshire in 1917; he, however, did not seek re-election to Parliament when the county was subdivided under the Act of 1918. He was also senior vice-president of University College of Wales, Aberystwyth, and the honorary degree of LL.D.Wales was bestowed upon him in 1922. He is survived by one son and two daughters.

GEORGE EDMONDSON BIRKETT, *M.C.*, M.R.C.S.

Director, Manchester and District Radium Institute

We regret to announce the death, at the early age of 37, of Dr. G. E. Birkett, which occurred on February 5th, and very unexpectedly even to his closest friends.

He was the son of George Birkett of Morecambe, and was born on November 26th, 1893. Educated at Lancaster Grammar School, he proceeded, with a scholarship, to Trinity Hall, Cambridge, where he took the natural science course with the B.A. degree in 1915. He then joined the Navy as surgeon probationer, continuing until ordered by the War Office to become qualified as soon as possible. He chose the Manchester Medical School, which he entered in 1916, obtaining the M.R.C.S. and L.R.C.P. diplomas in 1917. He then joined the R.A.M.C., and was sent to France. He was invalided home with pneumonia, but recovered well and returned to the front. There, in

1918, at St. Quentin, whilst carrying a wounded soldier to shelter, he was hit by a bullet in the lower part of the back. He received the Military Cross for this gallant action. An immediate laminectomy was performed abroad, and he was passed home to St. Thomas's Hospital, where he remained for over a year, undergoing subsequent operations. An injury to the cauda equina left him badly and permanently crippled in the use of his legs, and only allowed him to walk with great difficulty, and with the aid of a strong stick. In addition, he was subject to periodic spasms of intense neuralgic pain in the lower extremities.

In January, 1921, he was able to take on the duties of a house-physician in the Manchester Royal Infirmary, and at the expiry of the term of service he decided to take up the laboratory side of medicine. He became demonstrator in pathology in Manchester University, and pathological registrar at the Royal Infirmary in 1921. Here he showed himself to be a man of original thought and method, and proved to be a most capable and attractive teacher; clear, didactic, and just the type a student loves. In 1924 he became attached to the Manchester and District Radium Institute as pathologist, and the next year he was appointed acting director during long leave of the director, whom he eventually succeeded in 1926. In addition to his institutional work, Birkett acted as consultant over a wide area. He paid regular visits to Rochdale, Chester, Wrexham, and even as far away as Bangor to advise about the uses of the metal. He was attached to the staff of the Manchester Christie Cancer Hospital, and what pleased him greatly was that he was asked to be a member of the permanent advisory council of the new Mount Vernon Hospital. He was also an active and valuable member of the Manchester Committee on Cancer. His sound clinical sense and his wide experience of cancer, especially as it affected the skin, made his opinion on any doubtful case very valuable.

Birkett was of a nature that did not court publicity. He said little about the excellent work and the great needs of his own institute, contenting himself with his annual report. His best work in radium therapy was on the treatment of cancer of the tongue, mouth, and pharynx, and in this he obtained very great success with extraordinarily little disfigurement or disablement of the tongue. These results were achieved, not only with early cases, but with others that no surgeon would think of treating by excision or dissection. Birkett published several papers in scientific journals on the uses of radium, and a review of his latest monograph appears in the present issue of the *Journal*. Most of this book was prepared while the author was far from well, and its production is another instance of his doggedness. He was very much respected by the committee of the Institute, both for his personal merits and for his constant fight against physical odds. His early death is a great loss to them, and to cancer study and treatment, for his achievements gave promise of even greater relief to sufferers.

"W. H. H." sends the following appreciation:

Dr. Birkett's work as pathological registrar to the Manchester Royal Infirmary was an excellent training for what proved to be his life's work. His knowledge of the histology of malignant disease, on which he concentrated under the late Dr. Powell White, was extraordinary. The absence of any real surgical training was an accident which he himself deplored more than anyone, and this failing at times led him to exaggerate the value of surgery, which is a state of mind extremely rare in anyone enthusiastic in the development of a rival method of treatment. It guided him, however, along a sane course into unbiased judgement. Although radium has been investigated for medical purposes for over twenty years, he had been engaged in radium treatment for only six, and consequently the deductions from his work will have to be made by his successors. His mind was wholeheartedly in the subject. Handicapped by a deficiency in radium element, he was driven to the exploitation of emanation, in the use of which he possibly had few equals. It is probable, however, that during his last few months, when the National Radium Trust augmented his supply, his appreciation of the value of the element as against emanation was increasing. The simplicity of his thoughts helped him greatly in this empirical subject. He would never in any way consider dosage as such. Using the maximum amount of radium necessary to kill the malignant cell without even nearly approaching the danger line of necrosis, he concentrated on uniformity of distribution. In order to secure this he would move his needles to another site at the end of four or five days. He advocated needles, and deprecated the use of seeds. His radium supplies were too limited to use surface application extensively, and hence probably arose his great belief in the ultimate use of a modified bomb. Probably no one has produced better results in the buccal cavity, and his publications on the subject must have rescued primary cancer of the tongue from the hands of the surgeon. He realized to the full the limitations of radium. Insisting that the axillary glands in cancer of the breast could not be properly treated, particularly in stout subjects, by the blind insertion of radium needles, he invariably practised the open operation, with division of the lower part of the pectoralis major, so that he might accurately insert his needles into and around the glands themselves. As an earnest opponent of biopsy he diminished the value of his results; here, as elsewhere, he was thinking always of the good of his patient rather than of his statistics. His system of records and follow-up work was most thorough, and the knowledge gained therefrom was probably more responsible than any other factor for his successes. The amount of work he dragged from his, at times, painful body was truly remarkable, and his recent book, the preparation of which undoubtedly hastened his end, forms but a small part of his views on the value of radium. He realized that we are merely on the threshold of radium therapy, and we know that progress in this department will be retarded by his early death.

A. G. R. FOULERTON, O.B.E., F.R.C.S., D.P.H.

Consulting Medical Officer, East Sussex County Council

We regret to record the death of Mr. A. G. R. Foulerton, which took place rather suddenly at his home in London on February 2nd.

Alexander Grant Russell Foulerton was born at Exeter, the son of a Navy captain, in 1863. After studying medicine at St. Bartholomew's he qualified with the diplomas M.R.C.S., L.R.C.P. in 1884 and obtained the F.R.C.S. in 1895. In 1899 he was appointed bacteriologist to the Middlesex Hospital, and later became director of the cancer research and clinical laboratories there. In 1901 he was appointed medical officer of health for East Sussex, from which post he retired under the age limit in 1928, when the county council showed its appreciation of his services by appointing him honorary consulting officer.

When the European war broke out he was commissioned as a captain in the R.A.M.C., and after some service as surgeon to a home military hospital, was appointed D.A.D.M.S. to the principal sanitary officer of the British Expeditionary Force in France. In 1916 he was transferred to the hygiene department of the Royal Army Medical College, serving as sanitary adviser to the War Office. Here, except for a brief period with the U.S.

Expeditionary Force in Alsace, he continued until his retirement from the Army in 1919 with the rank of major.

Foulerton's authority and experience in bacteriology was widely appreciated, and he held various teaching appointments. At the time of his death he was lecturer in the public health department of University College, London, and lecturer on hygiene to the London School of Medicine for Women. He served as examiner in public health to the University of London and the Royal Colleges, and he had been Milroy lecturer to the Royal College of Physicians, his subject being "Tuberculosis and the streptotrichoses." He contributed a number of papers on pathological and public health subjects to textbooks and medical journals, and was joint editor of the *Review of Bacteriology*. At the Annual Meeting of the British Medical Association at Ipswich in 1900 he was honorary secretary of the Section of Pathology, and was vice-president of that Section at the Annual Meeting at Sheffield in 1908.

One great interest of his, outside his fields of technical work, was the London and Counties Medical Protection Society. He was one of the first members of that body, and after a period of service as auditor, he became, in 1895, its honorary financial secretary. The society's work and membership became so extensive that the post could no longer be an honorary one, and in 1905 Foulerton became financial secretary and vice-president, and was reappointed year after year until his death. The testimony of his fellow officers and members of council is that he was a charming colleague, also that he had a business capacity not often found in conjunction with high scientific attainments, and, further, that he had the keenest desire to help the working practitioner in his everyday perplexities and occasional misfortunes.

The funeral took place at Golder's Green Crematorium on February 5th.

The death took place at Bolton, on January 24th, of Dr. JOHN D. MARSHALL, who had been in failing health for over a year. Born in 1878, he received his early education at Bolton High School, and afterwards went to Manchester University, where he graduated M.B. with honours in 1905. In the following year he qualified M.R.C.S.Eng. and L.R.C.P.Lond., and later went to the Manchester Royal Infirmary as house-surgeon, and to St. Mary's Hospital, Manchester, as house-physician. Then for two years he was resident medical officer at the Victoria Hospital for Children, London. Returning to Bolton in 1908, he began practice, and soon became firmly established there. He made a special study of phthisis, and when the Wilkinson Sanatorium at Astley Bridge was opened he was appointed medical officer, a position which he held until forced to resign last year on account of his health. Dr. Marshall's Army record was a distinguished one. He was regimental medical officer with the Suffolk Regiment in France, and took part in many important engagements, once being seriously wounded. He was twice mentioned in dispatches, and was awarded the D.S.O. After the war Dr. Marshall resumed practice in Bolton, and was for some time president of the Bolton Medical Society. He had little leisure, and in 1929 his health broke down, forcing him to give up practice at the end of the year. Dr. Marshall's sympathetic and genial personality will be much missed in Bolton, and although a man of few words, his individuality gained for him the devotion of all his patients. He was a member of the British Medical Association for more than twenty years. He leaves a widow and two children.

Dr. RICHARD LEWIS, deputy medical officer of health and school medical officer for Carnarvonshire, died in Liverpool on January 23rd. He obtained the Scottish triple qualification in 1902, and the Diploma of Public Health in 1912. Not long after qualification he went on a voyage as ship surgeon, and during his appointment had to deal with an outbreak of yellow fever on the Amazon, in which he was successful. He served in the Army, both at home and in France, for practically the whole of the war period, and in the influenza epidemic of 1918 he seriously undermined his health by overwork at a military camp. His public duties were conscientiously carried out, and his skill as a diagnostician was well known. He was especially fond of children, and had an instinctive understanding of the child mind. He will be missed by a very wide circle, for he was a man who won great affection for his loyalty and his understanding. His was an admirable character, and his passing leaves a blank, not only where his own work was concerned, but also in the lives of his many friends. He had long been a member of the British Medical Association.

We regret to announce the death of Dr. FORREST BRECHIN of Renfrew, which occurred suddenly on January 27th in Glasgow. Educated at Glasgow High School and Glasgow University, he obtained the M.B. and Ch.B. degrees in 1904, and later took the Diploma of Public Health of Liverpool. After graduation he was appointed house-surgeon at Southport Infirmary, and later acted as assistant at Coatbridge. About twenty years ago Dr. Brechin took up practice in Renfrew, where he rapidly built up an extensive connexion, and where, owing to his striking personality, his common sense, and his high ideals, he was universally popular. He was an active member of the British Medical Association, and of the Renfrewshire Panel Committee, of which he was secretary. He was also medical officer of health for the borough of Renfrew, medical officer to the post office, and police surgeon. Dr. Brechin will be very much missed, especially for the warm and sympathetic nature which lay beneath a somewhat reserved exterior. His life was an inspiration and an example to all, and his loss is mourned throughout the district. He leaves a widow and one daughter.

Dr. GEORGE CLOWE CRICHTON, who died at Herne Bay on January 23rd in his eighty-fifth year, had a long record of work as a general practitioner, both in Twickenham and in Kensington. Graduating M.B., and L.R.C.S. at Edinburgh in 1875, he became house-surgeon at the Lancaster Infirmary, and after a short assistantship began his work in Twickenham, where he remained for about twenty years, being honorary medical officer of St. John's Hospital and medical officer of Twickenham Provident Dispensary. He was always proud of the fact that he was one of Lister's pupils at Edinburgh University, and it was he who introduced the methods of that famous surgeon to St. John's Hospital. When he went to Kensington he soon acquired a large practice. He was much beloved by his patients, particularly by children. Several years ago he retired to Herne Bay. For many years he was a member of the British Medical Association, and also of the old Therapeutical Society and of other scientific bodies. He was twice married, and leaves one son and one daughter.

By the recent death of Dr. ROBERT T. HERRON, Armagh has lost one of its most distinguished citizens. Born in 1864, he was educated at the Royal School, Armagh, and qualified L.R.C.S.I. in 1883, and L.M. in 1885. In 1904 he became M.R.C.P.Ed., and in 1905 M.D.Durham. He also obtained the D.P.H. of the Irish Conjoint Board in 1910. He had a strenuous medical, military, and athletic life. His Army record included service in South Africa from 1901 to 1902, for which he received the medal with four clasps, and in the great war he was mentioned in dispatches, retiring with the rank of major. His civilian activities were numerous; he was surgeon to the Armagh board of guardians, the prison, the military depot, Macan Asylum for the Blind, and Shiels's Institution. Dr. Herron took a great interest in the antituberculosis

campaign in Ireland, and gave lectures in many parts of the country. As a sportsman he was well known. In early life Rugby football was his favourite recreation, and for several seasons he acted as captain of the Armagh XV. Hunting and walking were also sports which interested him, and socially he was very popular. He was an active member of the Portadown and West Down Division of the British Medical Association. The funeral took place at St. Mark's Churchyard, Armagh, and was largely attended.

Dr. PAUL TRENDELENBURG, professor of pharmacology in the University of Berlin, died on February 4th, after a long illness, borne with great fortitude. Paul Trendelenburg was one of the best-known pharmacologists in Germany, and a man of great personal charm, whose loss will be greatly regretted by many friends whom he made when at Freiburg im Breisgau before the war and also in the various appointments he has held since.

The following well-known medical men have recently died: Dr. CARL GUTMANN, director of the dermatological department of the Wiesbaden Municipal Hospital; Professor SOMA BECK, director of the dermatological clinic at Fünfkirchen; Dr. PUIG, a prominent Paris stomatologist; and Dr. JUAN ALBA CARRERA, formerly assistant professor of toxicology at Buenos Ayres.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons spent two days this week on agricultural legislation, and two days discussing national economy and unemployment. A Prohibition Bill was the first order for Friday.

Bills

The Hospitals (Relief from Rating) Bill, introduced by Mr. Llewellyn Jones and supported by Dr. Fremantle, was down for second reading on February 6th, but was not reached. The prospect of its discussion this session is now small.

A Sentence of Death (Expectant Mothers) Bill, "to prohibit the passing of sentence of death upon expectant mothers and for other purposes connected therewith," was presented on February 4th by Miss Picton-Turbervill and read a first time. Its backers include Mr. Somerville Hastings.

Notice of presentation of a Bill for the registration of osteopaths was given for February 11th in the House of Commons.

National Health Insurance

Answering Mr. Womersley, on February 5th, Miss LAWRENCE said the subcommittee of the Approved Societies Consultative Council had not yet completed consideration of the question of ophthalmic benefit. She added that Mr. Greenwood had no evidence that the operation of Section 25, para. 5 (*b*), of the National Health Insurance (Additional Benefits) Regulations, 1930, had resulted in unsuitable ophthalmic treatment or apparatus being provided for insured persons. A society had authority, if it had good reason for doing so, to withhold consent to a member obtaining glasses from an optician who was not a member of an organization recognized by that society.

In a reply to Mr. Freeman, on February 5th, Miss LAWRENCE said that, so far as Mr. Greenwood knew, no hospital was included in any list of persons supplying drugs, medicines, and appliances under the National Health Insurance Acts.

On February 5th Miss LAWRENCE told Sir Kingsley Wood that Mr. Greenwood had decided to revoke Clause 4 (4) of the terms of service of insurance chemists, which covered the prohibition of the payment of co-operative dividends on national health insurance prescriptions. The representative bodies concerned had been informed.

Red Cross Rheumatism Clinic

There has, Miss LAWRENCE told Mr. Graham White on February 5th, been a steady and gratifying increase in the work of the British Red Cross Clinic for Rheumatic Diseases at Peto Place. To assess the results obtained would be premature. Mr. Greenwood would give careful attention to proposals made for extending the treatment of rheumatism. The Ministry would like to watch the experiment a little longer before acquainting local authorities with its results.

Local Health Services.—Dr. Fremantle was told, on February 5th, by Miss LAWRENCE that the initial surveys by Ministry of Health officers of the health services of local authorities would be completed in about two years' time. Dr. FREMANTLE asked if no action could be taken till then. Miss LAWRENCE said she would not go so far as that.

Tuberculosis.—Dr. FREMANTLE asked, on February 5th, when the Minister of Health would publish the memorandum on human and bovine tuberculosis, promised a year ago. Miss LAWRENCE said the memorandum was being printed, and would be published at an early date.

Deaths from Small-pox.—Mr. GREENWOOD stated, on February 4th, that the number of deaths of children under 2 years of age registered in England and Wales during 1930 in respect of which small-pox was mentioned on the medical certificate was seven. During the same period there was registered in England and Wales the death of one child under 2 years in respect of which vaccination was mentioned on the medical certificate. This death was classified to "pyaemia." Mr. GREENWOOD, replying to Mr. Freeman on February 10th, said that only six deaths from small-pox were recorded as having occurred among London patients in 1929. All these patients were unvaccinated. In two cases no cause of death other than small-pox was mentioned on the death certificate.

Disposal of London Refuse.—Miss LAWRENCE, in reply to a question by Dr. Fremantle, told the House, on February 5th, that Mr. Greenwood had received a report from the Standing Joint Committee that eleven metropolitan sanitary authorities favoured centralization in the disposal of house, trade, and street refuse from London, but eighteen were against it. To introduce legislation this session was impracticable, but the question would receive the Minister's further attention.

R.A.F. Invalidity Rates.—Mr. MONTAGUE, replying on February 3rd to Mr. Hore-Belisha, said that, during the year 1930, 174 airmen were invalided from the Royal Air Force, and in 16 cases the invaliding disability was considered to be attributable to the conditions of service. During the same period 22 airmen suffering from consumption were invalided, of whom 9 were accepted as attributable. Sixteen disability pensions were awarded during the year, and pensions in respect of service were awarded in 5 other disability cases.

Telephone Charges.—On February 9th Mr. LEES SMITH, replying to Sir W. Brass, said he regretted that in the application of telephone rates he could not discriminate between doctors and nurses and subscribers engaged in other businesses or professions. He could not state what would be the cost of reducing the business rate to that of the residential rate for such subscribers, but it would be large and increasing.

Health of Merchant Seamen.—Mr. W. GRAHAM, replying to Mr. Hastings and Dr. Morris-Jones on February 10th, said that the advice of the Interdepartmental Committee on the Health of the Mercantile Marine on the various questions referred to it from time to time by the Board of Trade or the Ministry of Health, was submitted to the Departments as the committee's consideration of each subject was completed, and no general report was published. The inquiry into seamen's mortality statistics was proceeding satisfactorily, but would take some time to complete. The question of crew spaces had been engaging the special attention of the Board of Trade, of the Joint Committee of the Board of Trade and Ministry of Health, and of the Shipping Federation. Draft instructions to surveyors had been placed before the Merchant Shipping Advisory Committee, and he hoped soon to be able to make a statement on the subject.

Medico-Legal

FIRST AID IN STREET ACCIDENTS

I. C.C. REPLY TO A JURY RIDER

In a recent trial for manslaughter at the Central Criminal Court the jury adder a rider, which was endorsed by the judge (Mr. Justice Charles), reflecting upon the ambulance service of London. An ambulance had been called to an accident case at Greenwich, where a woman had been knocked down by a motor cyclist. She appeared to be suffering from concussion, and had scalp and face wounds, and while the attendant was bandaging the wounds as she lay in the roadway a motor car was driven through the onlookers, caught the patient, and carried her for several yards, one wheel going over her body. She died two hours after admission to hospital. The driver was charged with manslaughter, but was acquitted, and the jury said there was negligence on the part of the ambulance authorities, while the judge said that it was a wrong practice to bandage people in the middle of the road; the injured person should be removed to the pavement. Sir William Willcox, who had been called on behalf of the defendant, had given a similar opinion in the witness-box.

The Central Public Health Committee of the London County Council now states that the opinion of the judge and jury, and of Sir William Willcox, is not supported by medical opinion generally or by those who have experience of, or are responsible for, ambulance services. It maintains that a principle in first aid is that the person apparently seriously injured should be allowed to remain in the place where he has fallen until he has been examined by a doctor or a person skilled in first aid. It is held to be extremely dangerous to move a patient who has sustained severe head or spinal injuries before first aid has been given, and in this case a local practitioner who saw the deceased after the first accident was of the opinion that she ought not to be moved. Representatives of the Order of St. John and the British Red Cross Society have expressed to the committee the same general views and advice that the patient should not be moved until first aid has been given appears in the textbooks of both bodies. It is added that the number of street accident cases dealt with by the Council's ambulance service in 1930 was 34,529, that this method has been employed ever since the ambulance service was started, and that the case under review is the first of its kind which has occurred. Notwithstanding the opinion of the judge and jury, and of Sir William Willcox as expert witness, it is proposed to keep to the established practice, which is in accord with up-to-date medical opinion and the advice of the Council's own officers; it is considered that it would be highly dangerous to issue an instruction to the ambulance staff that injured persons are not to be treated where they fall.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE.

At a congregation held on February 6th the following medical degrees were conferred:

M.D.—*S. D. Sturton.

M.B., B.CHIR.—W. G. Oakley, T. C. Stevenson.

M.B.—A. W. Williams.

* By proxy.

CONJOINT BOARD IN ENGLAND

The following candidates, having now passed the final examination in pathology, medicine, surgery, and midwifery, and having complied with the regulations of the board, are eligible to receive the diplomas of Licentiate of the Royal College of Physicians and of Member of the Royal College of Surgeons:

K. Alman-Vtcherachnia, W. Aukin, W. S. Baxter, H. W. Benham, A. I. P. Brown, A. L. Climer, P. Cohen, M. K. Cusack, D. M. Dean, W. F. T. George, J. B. Great Rex, W. H. Hargreaves, R. Herring, D. T. Ishmael, B. W. Knight, G. A. M. Lintott, Muriel H. E. Long, D. G. Macdonald, W. F. McGladdery, G. D. McLean, G. W. May, D. Nagarajan, C. E. S. Oxley, H. J. C. Page, C. F. Price, E. T. Renbom, B. Rubinsky, H. Silverberg, D. O. C. Simpson.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the College was held on February 3rd, when the president, Sir Norman Walker, was in the chair. Dr. William Archibald Mein (Bournemouth), Dr. Agnes Rose Macgregor (Edinburgh), and Dr. James Davidson (Edinburgh) were introduced and took their seats as Fellows. Dr. Ernest Watt (Edinburgh) and Dr. George Matheson Cullen (Edinburgh) were elected Fellows. Dr. H. C. Elder (Edinburgh) received a certificate of qualification to lecture in tuberculosis.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

Dr. G. Bewley has been nominated for the professorship of preventive medicine and medical jurisprudence in the Schools of Surgery, Royal College of Surgeons in Ireland.

Professor V. M. Synge has been appointed supplement examiner in medicine.

The following, having passed the necessary examination, have been admitted members of the college: J. F. Cunningham and P. T. J. O'Farrell.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The quarterly meeting of the council was held in London on January 24th. The president (Professor W. Blair Bell) was in the chair.

The president handed over to the College, in the name of his wife, the seal of the college, and from himself a set of dies for printing the Arms of the College (1) in colour, (2) in monochrome, (3) for plain printing.

The report of the Examination Committee on a number of applications for membership of the College was adopted, and the recommendations of the Fellowship Committee regarding promotions from Membership to the Fellowship were accepted.

Subcommittees were appointed to consider various matters connected with a maternity service for the country, and with the education of medical students in obstetrics and gynaecology, in accordance with resolutions of a special council meeting held previously.

Medical News

The next quarterly meeting of the Medico-Psychological Association will be held at B.M.A. House, Tavistock Square, W.C.1, on Wednesday, February 25th; Dr. T. Saxty Good will take the chair at 2.30 p.m. A paper on the utility of the psychiatric out-patient clinic will be read by Dr. Ian Skottowe, and, if time permits, Dr. Norman Phillips will read a paper on mental disorders associated with pernicious anaemia.

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, February 26th, at 8.30 p.m. Mr. Robert Churchill will read a paper on the forensic examination of firearms and projectiles. A discussion will follow.

At the next meeting of the Royal Microscopical Society, to be held at B.M.A. House, Tavistock Square, W.C., on Wednesday, February 18th, at 5.30 p.m., Professor Robert Chambers of New York will deliver a communication on "The nature of the living cell," with demonstration by micro-dissection, micro-injection, and cinematograph.

The nineteenth annual series of Chadwick Lectures will open on Tuesday, February 24th, at 8 o'clock, at the Royal Sanitary Institute, Buckingham Palace Road, when Mr. E. A. Elsby, B.Sc., will discuss the problem of silicosis as an industrial disease, under the chairmanship of Sir William J. Collins, M.D. The spring programme will include also a lecture by Professor Major Greenwood on "Nerves and the public health," in which "nervous" illnesses will be considered in relation to industrial lost time and the work of the Industrial Health Research Board. All Chadwick Lectures are free, and no tickets are required. Further information as to dates and subjects may be had from Mrs. Aubrey Richardson at the offices of the Trust, 204, Abbey House, Westminster.

A special two weeks' post-graduate course in orthopaedic surgery will be held at the Royal National Orthopaedic Hospital, Great Portland Street, W.1, from March 9th to 21st.

A radium symposium will be held by the British Institute of Radiology (incorporated with the Röntgen Society) in the Reid-Knox Memorial Hall of the Institute on February 19th, at 8.30 p.m. Papers will be read by Mr. C. E. S. Phillips, on the preparation of radium salts for therapeutic use; by Professor E. N. da C. Andrade, on a model to illustrate the passage of an alpha particle in the neighbourhood of an atomic nucleus; by Dr. Roy Ward, on some aspects of radium therapy; and by Dr. A. Burrows, on the organization of the radium and *x*-ray cancer service in Australia. The fifth medical meeting of members for this session will be held on February 20th, at 5 p.m., when further papers will be read, chiefly by Liverpool workers.

The second of the series of monthly clinical demonstrations for medical practitioners will be given at the Hospital for Epilepsy and Paralysis, Maida Vale, W.9, on Thursday, February 26th, at 3 o'clock, when Dr. F. L. Golla will demonstrate. Tea will be provided, and those intending to be present are asked to send a card to the secretary.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 52. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1. The list of special courses arranged for 1931 is now available.

A new operating theatre, equipped with all modern appliances, has been opened at King Edward VII Hospital, Windsor. The equipment has been given by Sir Joseph Skevington, the senior surgeon, and his brother, in memory of their sister, Miss Kate Skevington, who for many years took an active interest in the institution.

Among the subjects to be discussed by the Illuminating Engineering Society at its next meeting, in the Lecture Theatre at the Home Office Industrial Museum, Horseferry Road, S.W., on Wednesday, February 18th, at 6.30 p.m., is the relation between intensity of illumination and visual capacity.

The Wellcome Foundation Ltd. is about to erect a new medical and chemical research building in London at the corner of Gordon Street and Euston Road on the site, 225 ft. by 135 ft., now partly occupied by its Bureau of Scientific Research. During many years the Foundation has maintained medical and chemical research laboratories, but recent developments have made it necessary to co-ordinate and extend these activities. The new building will furnish the additional accommodation required, and be provided with the most modern research equipment. Mr. Septimus Warwick, F.R.I.B.A., is the architect.

In the seventh annual report of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation, it is announced that seventy-eight applications for grants were received by the trustees in 1930, sixty-two coming from twelve different countries in Europe and Asia, and the remaining sixteen from the United States. The total number of grants made during the year was twenty-five, twenty-one being awarded to scientists of countries outside the United States. Among the investigators who have been assisted in the current year is Dr. George Barger of Edinburgh, for chemical work on the alkaloids of ergot. Special attention was paid again in 1930 to the general subject of nephritis. Applications for grants during the year 1930–31 should be sent, before May 1st, to Dr. J. C. Aub, The Collis P. Huntington Memorial Hospital, 695, Huntington Avenue, Boston, Massachusetts. At present researches likely to be favoured in respect of grants are those directed towards the solution of problems in medicine and surgery, or allied branches of science. Grants may be used for the purchase of apparatus and supplies for special investigations, or for the payment of unusual incidental expenses.

The issue of the *Urologic and Cutaneous Review* for January contains an interesting historical survey of the development of modern urological instruments by Dr. Leo Burger, professor of surgery at Los Angeles.

The following three tours have been arranged by the Bureau of International Medical Foreign Travel, Biberstrasse II, Vienna, from which further information can be obtained. (1) March 19th. Visit to the Italian and French Riviera and Algeria, including Venice, Milan, Genoa, San Remo, Bordighera, Ventimiglia, Mentone, where a visit will be paid to Dr. Voronoff's ape farm, Monte Carlo, Juan les Pins, Cannes, Marseilles, Algiers, Biskra, and Touggourt. (2) March 19th. Continuation of first tour to Spain and Morocco, with return journey through Paris, where visits will be paid to the Institut Pasteur and Mme Curie's Röntgen department, Strasbourg, Munich, Salzburg, and Vienna. (3) Tour from Bremen, on April 30th, to the United States, with visits to Vanderbilt and Bellevue Hospitals, New York; Pennsylvania University, Philadelphia; Walter Hospital, Washington; and University of Chicago.

Dr. Edward Scripture, professor of experimental phonetics in Vienna, has been elected a member of the International Society of Experimental Phonetics.

The millenary of the Arabian physician and anatomist Abou Bekir el Razi, commonly known as Rhazes, was celebrated recently at the Palais D'Orsay, Paris, at a meeting organized by the Association of North African Mussulman Students in France, and presided over by Professor Ménétrier, president of the Académie de Médecine, and Dr. Laignel-Lavastine, secretary of the International Society of the History of Medicine.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Treatment of Sciatica

BM/SRHH writes: Could anyone who has used the injection of quinine and urea hydrochloride solution for sciatica say whether the method is successful, as claimed by Hertzler in the *American Journal of Surgery*, October, 1926?

A Fixative for the Hair

"D." asks: Can any reader recommend a toilet fixative for the hair which will not promote dandruff?

Treatment of Obesity

"W. F. C." writes, in reply to "A. S." (January 31st, p. 205): All obese persons will lose weight on a properly constructed diet, properly carried out. Glandular defects need to be repaired. When weight is not lost under treatment an error has occurred, either in the construction of the diet or, more probably, in its application. I suggest

that "A. S." should place the patient under medical observation for a week, in bed and with strict supervision of diet, glandular treatment, etc. The error will then be discovered.

Natural Labour after Caesarean Section

Dr. CHAMANLAL M. MEHTA (Hospital for Women, Bombay) writes:—In reply to the query by "W. M." (November 22nd, 1930, p. 891), I bring to your notice the following case: Mrs K. B., now aged 27, was confined normally of a 5 lb. 4 oz. baby in 1922. Her second child was delivered in December, 1923, by a Caesarean section, for the reason given as relative disproportion of foetal head and pelvis; the child weighed 6½ lb., and was healthy. She was confined by me for her third, fourth, and fifth babies absolutely normally, with no deviation of any kind in the progress of labour, in September, 1926, July, 1928, and September, 1929, the children's weight at birth being 5½ lb., 6½ lb., and 7 lb. The uterus has stood the strain well. Pelvic measurements are normal.

Dr. C. FIRTH PETTINGER (Newcastle, New South Wales) writes: I have had two cases of natural labour, with living babies, following Caesarean section which I had performed previously, once for placenta praevia, once for eclampsia. One of these patients is again almost at full term, and hopes for a natural delivery; the other has twice been delivered naturally of living babies since the operation.

Income Tax

Request for Excessive Payment

"North" sent in his declaration of untaxed income in good time last year, but the local inspector pressed for figures to be sent in by a qualified accountant. This was done, and the gross liability was agreed finally at £30 less than the amount originally returned. This, however, took time, so that the complete statement of total income was not sent in until after an estimated assessment had been made. The inspector now requests, through the accountant, that the tax charged by the existing assessment should be paid and any excess claimed afterwards—by repayment if necessary.

*** We think that the inspector's attitude is definitely incorrect and would not be supported by his headquarters. "North" should, in our opinion, decline to pay more than is due after the assessment has been corrected, and would be justified in referring the matter to Somerset House in the event of the inspector adhering to his present position.

Purchase of Share of Practice

"K. C." has bought a share of a practice, and is paying off the capital sum involved in instalments of £400 per annum, plus interest at 5 per cent. He asks: "Am I liable to income tax for the annual repayments?"

*** He is liable to account for income tax on the amount of his share of the partnership profits, and in doing so cannot deduct either the annual repayments or the interest. As regards the former, it represents a "capital" transaction; the money received is not income to the recipient, and cannot be treated as a deductible expense by the payer. The interest is on a somewhat different footing. It is income of the recipient, but the payer is liable to account to the revenue for the amount of income tax thereon, but has the right of recouping himself by deducting tax from the interest when he pays it.

LETTERS, NOTES, ETC.

Glycerin in Midwifery

Dr. P. G. PRESTON (Nairobi) writes: I was much interested in Dr. Mackinnon's letter (*Journal*, December 6th) on "Glycerin in midwifery." When a house-surgeon I had the care of a certain number of cases of puerperal sepsis with torn perineum, and used glauramine and glycerin. I noted then that the hygroscopic effect of this mixture was that of reducing the oedema of the damaged parts. In one case the patient had large oedematous haemorrhoids, which subsided with the dressing; after this I used it regularly, and later on, when house-surgeon in a general hospital, I used a glycerin dressing on all cases of prolapsed oedematous haemorrhoids. Since coming out here I have made a regular habit of treating immediately all cases in which the perineum has been torn, no matter how small or large the tear, with a dressing of acriflavine in glycerin (1 in 500), and I am pleased to say I have had remarkably good results, the cases showing little or no sepsis, and healing up quite well and quickly. I agree that this kind of dressing does seem to inhibit the growth of bacteria and to have a soothing effect. I was however a little surprised to hear that glycerin alone apparently acts as a germicide, and for this reason I have always added such an antiseptic as glauramine or acriflavine.

The Common Cold

Dr. L. H. BOOTH (Sturminster Marshall) writes: Comment, which combined scepticism with hope, was made in an annotation in the *Journal* of January 24th with regard to further recent investigations into the origin of the common cold. I believe it to be true that the common cold is primarily an acute inflammation following an irritation: in my ignorance I am unable to find valid reason why such inflammation should be caused by any one specific organism or filterable virus—any more than inflammation of mucous membranes elsewhere in the body is caused by only one specific agent. If it is not erroneous to argue that a cold is an inflammation, it would seem to be not unreasonable to infer that the process is essentially an effort on the part of Nature to get rid of a toxin—of classification variable—and subsequently to proceed to repair of the damage done. If that be so, I submit, in all reverence, that it is a matter for which we should thank God, just as also we should render thanks for the activity of other protective glands elsewhere. In my limited experience it has appeared evident that people who live habitually and continually in fresh air do but seldom acquire the symptoms of a common cold, be their nasopharyngeal flora what they may. When such symptoms do arise they are generally concomitant with others when resisting powers, including liver functions, are upset by another ailment. I believe that much could be done—perhaps is being done—by way of education to minimize the incidence of the common cold, by including in lectures on bodily hygiene, and teaching in school clinics, as well as in the home, the dutiful art of blowing the nose correctly, regularly, and at appropriate times, just as the need for the establishment of the habit of other bodily attentions is taught.

Painless Labour

Dr. C. J. DE VERE SHORTT (Liverpool) writes: A primipara, aged 19, engaged me for her confinement, due on December 25th, 1930. Six weeks before this date I was called in to see her on account of acute abdominal pain, which was localized to the epigastrium. There was no sign of dilatation of the os. Three days later she had recovered, but had developed a general pruritus, which did not respond to treatment. On December 9th she consulted me on account of the irritation, and I took the opportunity of examining her bimanually. I found the os half dilated, but she said she had no pain. I sent her home, and on visiting her next morning found she had had a good night's sleep and no pain. The os by this time was almost fully dilated. At about 11.45 a.m. dilatation was complete, and I delivered the child by forceps. The patient had an uneventful puerperium; four days after the birth of the baby the pruritus disappeared. Some years ago I had a similar case in which, however, there was a dull ache in the groins, not only when the uterus contracted, but during the whole time the os was dilating. To me the question of interest is: Is there a toxaemia present which causes anaesthesia of the nerve supply to the uterus, or is the condition merely one of Nature's freaks? Both patients were of the type that could not stand much pain.

Bradshaw's Continental Handbook

In 1847 George Bradshaw, a Manchester printer who had founded the well-known railway guide, began to publish a Continental Bradshaw. This consisted at first of a few pages of foreign time-table information, which was produced as a single volume, containing both time-table and descriptive pages, until 1914. When publication recommenced after the war these descriptive pages formed a supplement to the time-tables. The supplement is now issued independently at 3s. 6d., under the title of *Bradshaw's Continental Handbook for Travellers through Europe, etc.* All European countries come under its purview, and the "etc." includes such places as Algeria, Tunisia, Morocco, Egypt, the Sudan, and Palestine. It includes also a directory of bathing resorts and spas.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 51, 52, 53, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54, 55, and 56.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 51.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

141 Erythema Nodosum and Pulmonary Tuberculosis

H. d'U. A. ENGELSGAARD (*Tidsskrift f. d. Norske Laegefor.*, December 1st, 1930, p. 1311) has investigated the records of Lyster Sanatorium from 1914 to 1929, and has found that among the 4,991 patients treated there for chronic pulmonary tuberculosis during this period there were 155, or 3.01 per cent., who gave a history of erythema nodosum, the diagnosis of which had been made by a doctor. In the earlier years no systematic inquiry had been made for such a history, and when such an inquiry was undertaken during 1929 it was found that as many as 21, or 5.9 per cent., of the 356 patients admitted this year gave a history of erythema nodosum. Of the 155, only 31 were males—a ratio of 1 to 4. The average age at which the erythema occurred was 21; there were only 21 under the age of 15, and only 20 over the age of 30. As many as 82 stated that they had tuberculous parents or brothers or sisters, and in most of these cases the patients were in contact with their sick relatives when the erythema appeared. In as many as 55 cases the pulmonary tuberculosis became clinically manifest within three months of the outbreak of the erythema; and in 75 cases (including the 55 already mentioned) there was an interval of less than a year between the outbreak of the erythema and of the first clinical manifestations of pulmonary tuberculosis. No fewer than 120 of these 155 patients were already in the second or third stage (Turban-Gerhardt) of the disease, and 84 were sputum-positive. It would therefore seem that among the patients with a history of erythema nodosum the severity of the subsequent pulmonary tuberculosis was on the average relatively great. Only in 6 cases, or 3.2 per cent., was there a history of rheumatic fever.

142 Abdominal Symptoms in Acute Rheumatism

J. J. J. GIRALDI (*Arch. Dis. in Child.*, December, 1930, p. 379) records six cases to illustrate the point that digestive disturbances precede the onset of acute rheumatism more frequently than is generally realized. He believes that this implies a peritoneal reaction to the infection. The abdominal symptoms may be so serious as to suggest the need of a surgical operation, but he holds that there is no justificaton at present for such a term as "rheumatic appendicitis," although an acute appendicular inflammation may be simulated. Acute peritonitis at the onset of an attack of acute rheumatism is, he believes, a very rare phenomenon, but there is not infrequently in such cases evidence of the invasion of the peritoneum by the rheumatic virus. Giraldi concludes that these abdominal manifestations are worthy of closer consideration than they have yet received, since they may throw some light on to the pathogenesis of this infection. The presumed immunity of the peritoneum to infection is, he adds, more apparent than real.

143 Syphilis in Morbus Cordis

A. S. WARTHIN (*Amer. Heart Journ.*, December, 1930, p. 163) believes that syphilis plays a more important part in the production of coronary disease than has hitherto been recognized. Among 1,675 necropsies on individuals over the age of 25 during the last twenty years, he has found that 408 males and 86 females showed microscopical lesions of active latent syphilis. These consisted of perivascular infiltrations of lymphocytes and plasma cells around small vessels, with obliteration of the arterioles and resultant fibrosis. Such lesions involved the aorta in 90 per cent. of cases, and rather less frequently the meninges, testis, and heart. Active syphilitic lesions of the larger coronary branches were infrequent, and it was only rarely that occlusion of the vessel, thrombosis, or infarction followed. On the other hand, comparison between the latent syphilitic and non-syphilitic groups showed in the former a greater frequency of arteriosclerosis, occlusion, and thrombosis of the coronary vessels; the incidence of angina pectoris and myocardial infarction was also higher among patients suffering from latent syphilis. The author concludes that syphilis predisposes secondarily to coronary and aortic sclerosis. Comparing the syphilitic and non-syphilitic necropsies, sudden cardiac death appeared five times more often in the former than in the latter group. In the majority of cases such sudden death was the result of cardiac insufficiency and dilatation. This had resulted from a slight diffuse interstitial myocarditis which had led to myocardial fibrosis.

144 Varicella with Blood Picture simulating Leukaemia

D. GOLDMAN (*Amer. Journ. Dis. Child.*, December, 1930, p. 1282) records the case of a boy, aged 3, who on the second day of chicken-pox had a blood count of 76,750 leucocytes per c.mm., 89 per cent. of which were lymphocytes. The smear closely resembled that of lymphatic leukaemia, the difference being that only 2.5 per cent. of the cells were the larger less mature forms, most of them being of the small lymphocyte group. The tonsils were somewhat enlarged, and there was slight generalized adenopathy. The chicken-pox lesions on the body were larger, and remained pustular somewhat longer than usual. Mild diarrhoea persisted through the acute stage and until the fourth week. At the height of the disease the temperature was 102.8°. A fortnight after admission the white cells numbered 79,350, and the lymphocyte percentage was 86.5. The urine and stools were normal, the Wassermann reaction was negative, and no enlarged glands were found in the mediastinum on *x*-ray examination. Thirty-three days after the onset, when the total white blood count and the differential count had returned to normal, vaccination was performed, but no lymphocytic reaction reappeared in the blood; the injection of typhoid vaccine also failed to produce any change. Although leukaemia-like blood pictures are frequently seen in whooping-cough, no similar observations have been recorded previously in varicella.

Surgery

145 The Diagnosis and Frequency of Tuberculosis of the Knee

H. SUNDT (*Tidsskrift f. d. Norske Laegefor.*, January 15th, 1931, p. 73) reviews 310 cases of disease of the knee admitted to the coast hospital at Stavern since 1911. Tuberculosis was diagnosed in 205 (66.1 per cent.), while the remainder were classed as non-tuberculous. While the ratio of tuberculous to non-tuberculous cases was thus 2 to 1 for the whole of the nineteen-year period, it was 1 to 1 during the last four years; of 95 patients admitted between July 1st, 1926, and June 30th, 1930, 48 were diagnosed as tuberculous and 47 as non-tuberculous. While this change in the relative numbers of tuberculous and non-tuberculous cases may have been partly determined by the fact that more adults were admitted to the hospital during the four-year period, the most important factor in the recognition of an increasing proportion of non-tuberculous cases was the greater frequency with which the knees were explored by operative means. During the whole of the nineteen-year period 131 patients underwent a therapeutic or a diagnostic operation, and as many as 116 of these patients were operated on after July, 1919. During this latter eleven-year period the microscopical examination eliminated many cases which would have been labelled as tuberculous on the strength of a post-operative macroscopical examination. The author considers that, as far as adults are concerned, there

should be no hesitation in performing exploratory arthrotomy in doubtful cases; even in the case of children such an operation may be justifiable. An exploratory excision has saved many a patient at the Stavern Hospital from years of conservative treatment for tuberculosis and from the depressing effects of such a diagnosis. Among the 205 patients found to be suffering from non-tuberculous diseases of the knee during the nineteen years under review, there were as many as 55 to whose disease no name could be put. There were 21 cases of syphilis, 11 of arthritis deformans, 7 of osteomyelitis, 3 of haemophilia, 3 of osteochondritis dissecans, 2 of hysteria, and one each of chondrosarcoma gigantocellulare genus, xantho-fibro-sarcoma, and chondropathia patellae.

146 Mixed Renal Tumours in Infancy and Childhood

Reporting 17 cases of malignant renal tumours in infants and children, H. L. KRETSCHMER and W. G. HIBBS (*Surg., Gynecol. and Obstet.*, January, 1931, p. 1) state that the true nature of the neoplasm was not recognized either at operation or at the first histological examination. While the kidney is not the only organ to be affected by malignancy in children, it is the most frequent site, and the commonest type is the mixed tumour of Wilms. The embryonal structure of these tumours is their most distinguishing feature, with a variety of tissue of abortive renal elements. Extensions and metastases are exceptional unless the original tumour is large. Regional involvement by extension is the usual method of growth. Sex is not often of diagnostic value, though in the present series 14 were males. The eldest child was 6½ years old and the youngest 3 months. The duration of onset varied from six days to twelve months. Pain in the region of the tumour was present in five cases. Frequency of urination was noted in only one instance, and haematuria, so common in adults, was never observed. Fever was present in nine cases. In ten the growth was on the left side (the reverse of the usual site), and in two there was bilateral involvement, an extremely rare occurrence. In every instance the tumour was palpable, and secondary anaemia was definitely present. The authors find that the diagnostic problem does not differ from that in adults. Cystoscopy and ureteral catheterization should be performed in all cases in order to obtain a pyelogram and to determine the function of the opposite kidney. The authors emphasize the importance of ensuring the presence and healthy functioning of a second kidney before performing nephrectomy, and give a warning about the possibility of bilateral involvement.

147 Adenocarcinomatous Growths of the Bladder

R. C. BEGG (*Brit. Journ. of Surg.*, January, 1931, p. 422) points out that colloid adenocarcinomata, resembling rectal growths may arise as primary tumours in the muscular wall of the upper part of the bladder, and that there is a general tendency for neoplasms in this region to assume the form of colloidal cancer. Primitive cells of the urachus are always present in the muscular wall at the bladder apex and, when active, form tumours of the intestinal type. Adenomatous and various kinds of cystic formations are commonly found in connexion with the lower end of the urachus, and show various degrees of close relationship to the colloid cancers. Begg concludes that all tumours of the bladder apex must be assumed to be of urachal origin from the point of view of treatment unless they can be proved to be otherwise. Radical operation is essential, comprising the removal of the umbilicus and of all the tissues between it and the bladder, as well as of a large portion of the vesical wall.

148 Thrombosis of the Axillary Vein

J. WULSTEN (*Zentralbl. f. Chir.*, January 10th, 1931, p. 72), who records an illustrative case, states that autochthonous thrombosis of the axillary vein is extremely rare. The first German case was reported by Schrötter in 1884, and the first French case by Meslay in 1894. No further cases were described until 1921, when Holländer recorded three more, though he stated that their causation was not clear. The principal factors in the production of axillary thrombosis appear to be, first, slowing and weakening of the circulation; secondly, infection; thirdly, damage to the endothelium; and, fourthly, change in the composition of the blood. Each of the factors may occur alone, but infection is indispensable for the formation of thrombosis. Treatment consists in rest of the limb. Wulsten's patient was a servant-girl, aged 17, who developed thrombosis of the left axillary vein due to hard work on a washing day and infection of an excoriation on the ring finger. Two months after the onset the patient had a violent attack of pain in the left hypochondrium with dyspnoea, suggesting pulmonary or splenic embolism, but these symptoms subsided in a week, and recovery took place under conservative treatment, although five months after the onset the patient's left arm was still larger than the right, and she was unable to do heavy work.

Therapeutics

149 The Prophylactic Value of Salicylates in Rheumatic Manifestations

C. B. LEECH (*Journ. Amer. Med. Assoc.*, September 27th, 1930, p. 932) has endeavoured to provide statistical evidence of the value of salicylates as a preventive of the recurrence of rheumatic disorders. To 67 children with potential heart disease and inactive rheumatic heart disease were given daily 20 grains of acetylsalicylic acid for a period of six months. The control group contained 79 children with similar potential and acquired rheumatic heart lesions. Fewer recurrences of chorea were noted in the experimental than in the control group. The control children did not do so well as the others in respect of gain in body weight, improvement in the heart rate, general bodily comfort, and actual physical capacity as judged by the functional classification based on ability to carry on normal activities without discomfort. Improvement in comfort seemed to play a part in allowing a more satisfactory gain in body weight. Almost without exception the children with recurrences of chorea lost weight before the recurrence, or only gained slightly. Apparently a child who gains weight normally is unlikely to develop chorea. Thus, by increasing the physical comfort of the child, and by facilitating gain in weight, the drug appears to reduce the incidence of attacks of chorea. The number of rheumatic recurrences in this series was too small, and the time too short, to allow accumulation of evidence in regard to any possible effect in preventing endocarditis as a sequel of chorea or other rheumatic manifestation. Leech concludes that his analysis shows that there is a definite advantage in giving daily rations of salicylates to children who represent actual or potential instances of rheumatic heart disease.

150 The Diet in Pulmonary Tuberculosis

J. OLSEN (*Ugeskrift for Laeger*, December 18th, 1930, p. 1194) has treated twenty-four cases of pulmonary tuberculosis on the following principles. The weakened organism should not be burdened with more food than is absolutely necessary; the dietary is therefore reduced to about 28–30 calories per kilo body weight. No trace of albumin in excess of the patient's needs should be given; his diet is therefore made as vegetarian as possible, the only animal foods allowed being butter, whipped cream, and buttermilk. The consumption of albumin is thus reduced to about 0.5 gram per kilo body weight, and the metabolism is diminished to the lowest possible limits. The motions are rendered as odourless as possible. The functions of the skin are promoted by means of heat and, when available, artificial light. The author treats his advanced cases by rest in bed, the patient being given on the first day as much boiled water flavoured with lemons as he likes, but nothing to eat. On the second day he may eat as much oatmeal gruel as he likes. On the third day this dietary is supplemented with oatmeal porridge and two slices of buttered toast. The menu is gradually increased till at the end of about a week he is receiving a sufficient supply of calories and proteins. Potatoes,

carrots, beans, and various other vegetables are given, also a little fruit. The patient drinks the juice of one lemon daily. Flavouring agents, tea, and coffee are strictly rationed, and milk, eggs, fish, and meat are forbidden. The author admits that in such a capricious disease as tuberculosis the many successes achieved among his twenty-four patients do not *per se* establish his case, which is that asepsis should replace antisepsis in medicine as it has done in surgery.

151 Treatment of Chorea

J. D. PILCHER and H. J. GERSTENBERGER (*Amer. Journ. Dis. Child.*, December 1930, p. 1239) report the occurrence of fever and a rash in the majority of children treated for chorea with phenyl-ethyl-hydantoin, a drug introduced in Germany about 1918 as a hypnotic and general sedative. In chorea the drug is administered in doses of from 0.1 to 0.15 gram (1½ to 2¼ grains) three times a day, in the case of patients up to 14 years old. Fever develops after six to nine days, rising gradually to 102°–104° F. a few days later, at which time a morbilliform rash appears, fading gradually in a few days as the temperature returns to normal. Severe cases react better than mild ones, and improvement usually follows promptly. Those cases that do not react are not appreciably benefited as a rule. It has been suggested that the reaction is of the nature of protein shock. Complications usually consist of irritation of the mucous membranes and more rarely of the urinary tract with blood in the urine; in one case there was an exudation into the lungs, causing a condition resembling pneumonia. These complications have not proved serious in children.

Anaesthetics

152 Percaine in Dental Operations

M. MELCHIOR (*Ugeskrift for Laeger*, November 20th, 1930, p. 1079) traces the development of local anaesthetics since the introduction of cocaine in 1884. He remarks that, with one exception, all the substitutes for cocaine which have been introduced since then have shared the same fate: great praise at first, followed by a waning reputation ending in oblivion. The one exception—novocain, introduced in 1905—has maintained its prestige. Percaine, introduced in 1929, has enjoyed the early enthusiasm of its predecessors. Various authorities in dentistry have praised the intensity and duration (up to several hours) of its action, but warning voices have already been raised with regard to its alleged toxicity, and its tendency to induce dilatation of blood vessels with consequent post-operative haemorrhage. After quoting the investigations of various authorities, the author refers to his own, which included a series of dental extractions effected on one side under percaine and on the opposite side and corresponding tooth under novocain. Percaine was first given in solutions of 0.5 to 1 per 1,000, but this strength was found to be totally inadequate. With a 2 per 1,000 solution of percaine, satisfactory anaesthesia was induced in only 7 out of a series of 12 cases, in five of which its action was only moderately successful, and in one of which it failed altogether. On the other hand, a 2 per cent. solution of novocain gave a more complete and reliable anaesthesia, and in but one case in this series was its action only moderately effective. The complete anaesthesia lasted about the same time, but the subsequent partial anaesthesia continued considerably longer in the percaine than in the novocain field of operation.

153 Infiltration Anaesthesia in Fractures

C. O. RICE (*Med. Journ. and Record*, November 5th, 1930, p. 423) advocates the employment of infiltration anaesthesia in the reduction of fractures, its only contraindication being the presence of infection or in compound fractures. Muscular relaxation as complete as under deep surgical anaesthesia can be obtained by infiltration with a local anaesthetic into the fracture gap so that the torn edges of the endosteum and periosteum become impregnated. By using a 1 per cent. procaine-adrenaline solution it was found that the period of anaesthesia was prolonged from four to ten times by the presence of adrenaline, and by slowly infiltrating ahead of the needle the pain associated with the process is minimized. Should anaesthesia and relaxation fail to occur after injecting from 5 to 10 c.cm. of the solution into the fracture gap, the periosteum of the proximal fragment is then infiltrated around its entire circumference. Whenever manipulation is undertaken to reduce a fracture this method of anaesthesia is preferable, as it is also if remanipulation of the fragments becomes necessary; better alignment can be obtained because the fragments can be adjusted under radioscopy. The method does not give rise to any untoward effects, nor does it interfere with healing.

154 Combination Anaesthesia

F. L. GRANDSTAFF (*Amer. Journ. of Surg.*, November, 1930, p. 300) records the result of 200 surgical cases in which complete or partial unconsciousness was produced by intravenous sodium iso-amyl-ethyl-barbituric acid (sodium amytal). The maximum dosage was 1 grain per 10 lb. of body weight, but allowances were made for certain factors such as temperature, thyroid dysfunction, age, cachexia, dehydration, and pre-operative medication. It was also found that patients with hypertension and arterio-sclerosis reacted more quickly to sodium amytal than others with a normal blood pressure, while alcoholics required the maximum dosage. The average dose required for laparotomy was 11 to 13 grains. Pre-operative treatment included 10 grains of chlorbutanol by mouth the night before, and again two hours before the operation, while morphine sulphate, with or without atropine sulphate, was given subcutaneously to all adult patients half an hour before the operation. A 10 per cent. solution of sodium amytal was injected intravenously, not more rapidly than 1 c.cm. per minute, and a supplementary anaesthesia of nitrous oxide and oxygen was afforded. The advantages of this form of anaesthesia were the diminishing of psychic trauma, and the reduction in quantity of inhalation anaesthetic required. Post-operative complaints of nausea and vomiting were absent in 95 per cent. of cases, and paresis of the intestinal tract, with flatulence, appeared to be less than with inhalation anaesthesia alone.

Obstetrics and Gynaecology

155 A Hormone Test for Early Pregnancy

Friedman has demonstrated that intravenous injection of 5 c.cm. of urine from a pregnant woman into a rabbit provokes ovulation as in a mouse subjected to the Aschheim-Zondek test, with this advantage, that in the former animal ovulation occurs within 24 hours, while in the latter it takes 100 hours. The results were so striking that P. F. SCHNEIDER (*Surg., Gynecol. and Obstet.*, January, 1931, p. 56) has employed this test in 100 cases to determine its clinical value. The factors involved in the test are enumerated. Into the marginal ear vein of a female rabbit, 12 to 14 weeks old, is injected from 5 to 7 c.cm. of the first morning urine passed by the woman being tested. The rabbit is killed 24 to 30 hours after the injection, and an immediate diagnosis is afforded by inspection of the ovaries. If the reaction is negative, these are found to be small and to be showing no change; if positive, one to fourteen corpora haemorrhagica and lutea are found in each ovary. Sometimes a positive result has been obtained in twelve hours. Schneider concludes that his results prove that the test is positive very early in pregnancy. It is simple, accurate, and can be completed within 24 hours; perfecting of the technique may reduce this time to 8 to 12 hours. The conditions from which early pregnancy can be differentiated by this test are mentioned. The rapid disappearance of the hormone after delivery, and the persistence of the reaction following incomplete abortion or foetal death, indicate its possible value in diagnosing retained decidual tissue after labour or incomplete abortion.

156 **Induction of Labour**

L. C. L. AVERILL (*New Zealand Med. Journ.*, December, 1930, p. 361) commends the induction of labour in New Zealand, where he thinks the children tend to be oversized. He considers quinine and pituitrin induction practically free from danger to the mother when properly conducted. It is especially advisable in cases of threatened disproportion in primiparae where the head remains floating at term. If the cervix is firm and well formed he uses the usual 0.5 c.cm. doses of B. P. Watson, but if it is soft and almost taken up before labour begins he gives 4-minim doses half-hourly for eight doses. Immediately any pains begin the injections are stopped. Averill believes that there is very little likelihood of the child being endangered.

157 **Changes in the Ureter during Pregnancy**

Dilatation of the ureter during pregnancy has been found at necropsy and operation, and thought to be concerned in the etiology of eclampsia. P. SCHUMACHER (*Arch. f. Gynäk.*, October 24th, 1930, p. 28), investigating by pyelography after the intravenous injection of uroselectan the anatomy of the ureter in physiological conditions in a hundred pregnant subjects, found that from the fifth month onwards there is invariably present a dilatation and diminution of tone in one or both ureters: both in 83, the right only in 15, and the left only in 2. This dilatation, which reaches a diameter of 2 to 2.5 cm., affects the abdominal portion only of the ureter, and by the eighth month is combined in four out of five cases with backward and outward displacement, and in the same proportion with kinking, either below the renal pelvis or at the junction of the upper and middle (abdominal) thirds.

158 **Trial Labour in Contracted Pelvis**

BROUHA (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, November, 1930, p. 739) reports a hundred trial labours in patients whose pelvic contraction was such that the antero-posterior diameter of the inlet ranged from 9.5 to 8 cm. In about one-half of the cases Caesarean section was avoided; the maternal mortality was *nil*, the foetal 4 per cent. The patients entered hospital as soon as labour commenced. Vaginal examination was made when the membranes ruptured (in order that prolapse of the cord, forbidding further expectant treatment, might be excluded), or at a cervical dilatation of 4-5 cm. When this was attained the membranes were artificially ruptured to shorten labour. With a conjugate of 95 cm. about one-fourth, and with one of 9 cm. nearly one-half, of the patients had eventually to have Caesarean section. PERY and MANGÉ (*ibid.*, p. 661) describe a case illustrating a danger of trial labour in contracted pelvis. The conjugate was very slightly reduced, the sacral promontory being just accessible, but the foetus weighed 4.85 kilos. The patient, a 1-para aged 20, had been fourteen hours in labour when Caesarean section revealed an unsuspected tear in the lower uterine segment; this proved to be so friable that hysterectomy had to be performed.

Pathology

159 **Immunology of Scarlet Fever**

W. R. F. COLLIS and A. G. WATKINS (*Arch. of Dis. in Childh.*, December, 1930, p. 441) report a case of scarlet fever in a boy, aged 2, which indicates that this infection is not a simple toxin-antitoxin phenomenon, and that the Dick test should be regarded merely as an indication of the presence of antitoxin in the patient's serum, and not as a guide to the general immunity of the patient to the specific streptococcus of the disease. Although the rash was quite transient, and none of the graver toxic symptoms of the scarlet fever syndrome supervened, yet the patient succumbed to a generalized septicaemic involvement of the spleen, lungs, kidneys, and serous cavities by the specific haemolytic streptococcus. The Dick reaction was negative at a time when it would have been expected to be positive. The authors distinguish two immunological states in scarlet fever: the specific toxic state, producing the usual exanthem, and those septic phenomena, such as pharyngitis, adenitis, otitis, and septicaemia, which are due to the specific organism. H. J. Parish and C. C. Okell have established the fact by animal experiments that the presence of antitoxin in the blood does not avert subsequent septicaemia. J. V. Cooke has shown that 90 per cent. of infants under the age of 6 months give a negative Dick reaction, and the present authors define this as the first or "pre-sensitive" stage; then comes a second or "hypersensitive" stage (Dick-positive); and finally, in older children and adults, whether they have had scarlet fever or not, a third "post-sensitive" stage, when there is sufficient antitoxin in the blood. The rash, vomiting, and pyrexia of scarlet fever would thus represent a hypersensitive response on the part of the patient to the specific toxin of the scarlatinal type of haemolytic streptococcus, rather than a general reaction to an infection with the organism itself. In the present case the child would appear to have reached the third or "post-sensitive" stage, his serum containing enough antitoxin to give a negative reaction to the Dick test, and to prevent the development of all the clinical symptoms of scarlet fever except the transient rash. The antitoxin did not, however, arrest the multiplication of the streptococcus in the blood, or avert the subsequent death from septicaemia complicated by acute nephritis.

160 **Allergy and the Acid-Base Balance**

Without disparaging the sensitization hypothesis of allergy, H. BECKMAN (*Journ. Amer. Med. Assoc.*, November 22nd, 1930, p. 1582) suggests that there may be an intimate connexion between allergy and the acid-base balance, and brings forward considerations which support this view. Diabetic patients, acidotic individuals, do not usually suffer from allergic diseases. Starvation, a cause of acidosis, appears to militate against allergy conditions, as also does pregnancy, during which the alkali reserve is sometimes much lowered. Other acidotic phenomena, such as acute pyrexia and the effects of sea voyages or sojourning at high altitudes, are also found to operate against allergic manifestations. Another argument cited is that the combination of whisky and acetylsalicylic acid, which causes a relative acidosis, is often effective in asthma. Beckman has found the administration of nitrohydrochloric acid to be curative in hay fever, and he suggests that ketogenic feeding should be tried in a carefully controlled series of asthma and hay fever cases. He believes that in the production of the allergic state other factors are concerned than sensitization alone.

161 **Asbestosis Bodies in the Sputum**

F. W. SIMSON and A. S. STRACHAN (*Journ. Path. and Bact.*, January, 1931, p. 1) report a series of examinations of the sputa of fifty workers in an asbestos mill, some of whom had also been exposed to this dust in other occupations. In forty-eight of these patients asbestosis bodies were found; they were as easily demonstrated by examining thick films directly as by the antiformin concentration method. In the absence of bronchial complications the sputum was always mucoid, and might even resemble egg albumen. In none of the sputa were tubercle bacilli demonstrated. A study of the intracellular asbestosis bodies in these cases suggested that they had been formed by the deposition on asbestos fibre of an iron-containing substance elaborated by the cell. The authors remark that it is obvious that the presence of these bodies in the sputum does not necessarily imply the existence of pulmonary fibrosis, although it does seem to indicate a reaction on the part of the alveolar epithelium. The stages in their development are as follows. The fibre becomes coated with a pale greenish-yellow or golden-yellow substance, which gives a prussian-blue reaction. This coating may be uniform, except at the extremities, where there is a bulbous enlargement. The deposit increases, and segmentation appears in some of the bodies; later the segmentation becomes deeper, and complete fracture of the fibre may occur with formation of the "crustacean" type of body.

What about taste?

MANY patients still believe innocently that the medicine must be bitter to be efficacious.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is for that up to date generation that wants its medicines in the proverbial "sugar coating."

No excuses are needed for its taste any more than for its effectiveness. Agarol Brand Compound is exceptionally palatable without artificial flavouring. It *flows freely* from the bottle, and can be mixed with any liquid or soft food.

Just enough mineral oil to carry unabsorbable moisture to the intestinal contents, keep them soft, and so make evacuation easy and painless. By *gentle stimulation* of peristalsis, Agarol Brand Compound makes the result certain; and aids in re-establishing regular habits.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

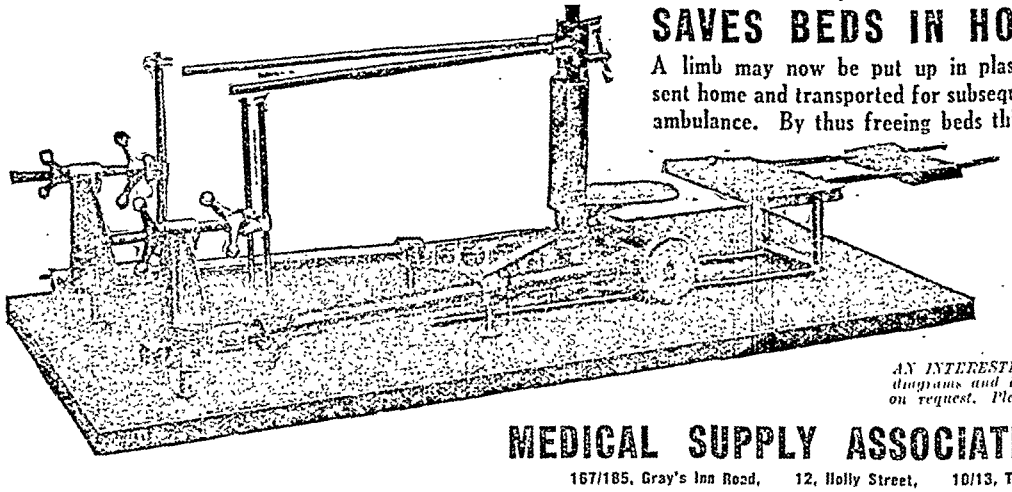
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

COLLENDER'S SPLINTS

(Patented in the leading countries of the world.)

An evolution of the Thomas splint, preserving all its advantages with many improvements.
Invaluable for Hospital, Emergency, and District Surgeons' work. Indispensable for Mines, Ranches, Lumber Camps, Railways, Shipping Cos., and all places remote from surgical aid. Made of Duralumin, untarnishable, light, and of great tensile strength. All parts interchangeable. Complete splints constructed in a few minutes for limbs of any dimensions. Sufficient members to accommodate ten fractures simultaneously. Supplied in strong fitted case.

WATSON BAKER COMPANY, WEST END LANE, BARNET, HERTS, ENGLAND

DEAF DOCTORS

AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me";* without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

NEW PREPARATIONS
OF THERAPEUTIC VALUE
By SAVORY & MOORE, LTD.

Products Supported by a Reputation of over 130 years.

FRUCTOLE CASCARA. An active preparation containing the full therapeutic value of Cascara Sagrada, without its bitter principle, combined with a pleasantly flavoured fruit base. An ideal Tonic Laxative.
In 2 oz., 4 oz., 8 oz., and 16 oz. bottles.

FRUCTOLE of SENNA PODS. A natural Vegetable Laxative containing Savory & Moore's specially prepared Liquid Extract of Senna. This preparation is free from the griping tendency which many Senna preparations are liable to produce.
In 2 oz. and 4 oz. bottles.

LIVER EXTRACT (Bell). A standardised highly concentrated preparation of full activity. Each maximum dose is equivalent to 8 ounces of Fresh Liver.
In 4 oz., 8 oz., and 16 oz. bottles.

ARSENIATED LIVER EXTRACT (Bell) combines with Liquid Extract of Liver valuable organic salts of Arsenic. For the treatment of Anaemia.
In 4 oz., 8 oz., and 16 oz. bottles.

VITAMIN EXTRACT of MALT and COD LIVER OIL (Toffee Flavour). A guaranteed product tested to a standard of Diastatic Power and Protein Content. High content of essential Vitamins A, B and D.
In 1 lb., 2 lb., and 4 lb. Jars.

Savory & Moore's Preparations are accepted by the entire Medical Profession as being representative of the highest quality and of greatest purity. An effective system of Analytical Control ensures that every constituent and every process in manufacture is of a standard only associated with the best of products.

SERVICE. No effort is spared to meet the varied requirements of the Profession.

RHEUMATOID ARTHRITIS

UNDER this name, several conditions which are ætiologically distinct are doubtless grouped together, and we are still far from a solution of the cause of the disease.

It is obviously impossible to restore in any marked degree mobility to the joints of the hopelessly crippled, but in the early stages much may be done to retard or stop the progress of the disease.

An eminent surgeon has directed attention to the rôle of chronic intestinal stasis and alimentary toxæmia in the production of the disease, and has emphasised the need for intestinal disinfection.

For this purpose nothing surpasses the use of Kerol Capsules. Kerol is a potent and non-toxic germicide which is unabsorbed from the intestine, so that the whole of its germicidal power is exerted upon the contents of the bowel.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A anacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Kliniek (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Celestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LIMITED,

Bangor Wharf, 45, Belvedere Road - - - - - - - London, S.E.1

And at LIVERPOOL and BRISTOL.

SPHYGMOMANOMETERS

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-therapeutic treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Billiards, tennis, etc. Fees from five guineas per week.

Apply, Dr. D. E. M. DOUGLAS-MORRIS. *Telephone*: Newport Pagnell 121.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Clifden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P. *Telephone*: Teignmouth 289.

Now removed to:

CHISWICK HOUSE, PINNER, MIDDLESEX.

Telephone: PINNER 234.

A modern country house, 12 miles from Marble Arch, in beautiful and secluded grounds.

Fees from 10 guineas per week.

Voluntary Patients received for treatment.

Special provision for "Temporary" patients under the new Mental Treatment Act.

DOUGLAS MACAULAY, M.D., D.P.M.

BARNWOOD HOUSE,
GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Medical Supt.
Telephone: No. 7 Barnwood.

FUNCTIONAL NERVOUS DISORDERS.

Telegrams: Castle, Ruthin. Telephone: 66, Ruthin. Ruthin Castle, North Wales.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

THE OLD MANOR SALISBURY

A Private Hospital for the Care and Treatment of those of both sexes suffering from MENTAL DISORDERS.

Extensive grounds. Detached Villas. Chapel. Garden and dairy produce from own farm. Terms very moderate.

THE TREATMENT OF GOUT

PISTANY

RADIO-ACTIVE MUD PACKS

PISTANY SPA REPRESENTATION,
38, Sackville Street, W.1. Tel. Gerrard 1238.

Pistany (Czechoslovakia) offers the most effective treatment for the cure of gout.

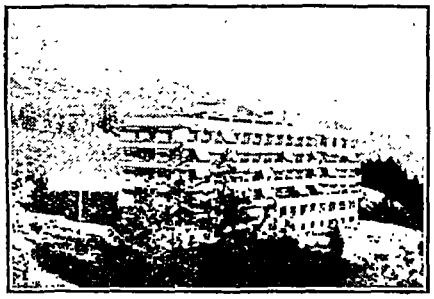
Special provision is made for the diet of gouty patients in the hotels.

In mild cases a few weeks suffice to relieve the condition but the need for prolonged intermittent treatment often makes a course with Pistany Mud Cubes or Compresses at home, under the patient's own doctor's supervision indispensable for a complete cure.

The method of application is safe and inexpensive for Pistany's sulphur Mud is inert and sterile of mineral content and keeps indefinitely.

Send for interesting Medical and Tourist literature.

MONTANA HALL, MONTANA, SWITZERLAND, *FOR BRITISH PATIENTS.*



For the treatment of TUBERCULOSIS, Diseases of the Chest, Asthma, for patients requiring rest in the Alps under strict medical supervision, and for medical conditions in which sun and air bathing are indicated. B. WAGSTAFF, Secretary.

County Council of Durham.

EDUCATION DEPARTMENT.

ASSISTANT SCHOOL MEDICAL OFFICER.

The County Education Committee invite applications for the post of Assistant Medical Officer, to act under the School Medical Officer in connection with the inspection of school children, and such other duties as may be required by the Education Committee. Commencing salary £500 per annum (providing the candidate has had not less than three years' *Post-Graduate experience*), *rising by* annual increments of £25 to £700 per annum, together with travelling expenses according to the County Scale. The successful candidate will be required to devote his (her) whole time to the duties of the office, and reside in or near the district to which he (she) will be attached at a place to be approved by the Education Committee. The appointment will be subject to three calendar months' notice on either side, expiring on the last day of any calendar month. Applicants must have had experience in the work of school medical inspection, and preference will be given to candidates who:

(a) Have had experience in the work of School Clinics.
(b) Have been accustomed to make special reports on Mentally Defective, Physically Defective, Epileptic, and other Defective Children.

The possession of a Diploma in Public Health is desirable, though not essential.

Copies of not more than three recent testimonials are required.

Canvassing, directly or indirectly, is prohibited, and will disqualify.

A deduction of 5 per cent. will be made from the salary in accordance with the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the County Council's medical examination in connection therewith.

Forms of application, to be returned not later than Saturday, February 28th, may be obtained from the Director of Education, Shire Hall, Durham, on receipt of stamped addressed envelope.

Shire Hall, Durham. THOS. B. TILLEY, Director of Education.
February 9th, 1931.

City of Birmingham Education COMMITTEE.

APPOINTMENT OF DIRECTOR OF CHILD GUIDANCE CLINIC AND SPECIAL SCHOOLS MEDICAL OFFICER.

The Birmingham Education Committee intend shortly to appoint a full-time Medical Officer to act in the following capacities:

(1) Special Schools Medical Officer;
(2) Director of the Child Guidance Clinic to be established in the near future.

Candidates should be fully qualified Medical Practitioners, have good experience in the treatment of diseases of children, and special knowledge of Psychological Medicine.

The salary offered is from £600 to £700 per annum, according to qualifications and experience.

A Fellowship will be available if necessary to enable the successful candidate to train in Child Guidance work.

The terms of the appointment may be subject to alteration at the end of three years.

Canvassing, direct or indirect, will be regarded as a disqualification.

Further information as to the conditions of the appointment may be obtained from the Chief Education Officer, Education Office, Council House, Margaret Street, Birmingham, to whom all applications should be addressed. Applications for appointment should give full particulars as to age, training, and qualifications, and should be posted in time to reach the Chief Education Officer by February 21st.

Education Department,
Council House, Birmingham.
January 21st, 1931.

WM. M. MOORE,
171, West Regent Street, Secretary.
Glasgow, C.2. February 6th, 1931.

Royal South Hants and SOUTHAMPTON HOSPITAL.

CASUALTY OFFICER required. Six months' engagement. Salary £120 per annum, with rooms, board, and laundry. Applications, stating age, to be sent to the undersigned, together with copies of testimonials (limited to five) as soon as possible.

HY. TRUSSON, Secretary.

Metropolitan Borough of Poplar.

MALE ASSISTANT MEDICAL OFFICER OF HEALTH (TUBERCULOSIS SECTION).

The Council of the Metropolitan Borough of Poplar invite applications for the above post from duly qualified and registered male Medical Practitioners who are specially qualified in the diagnosis and treatment of Tuberculosis, and not over 40 years of age.

The person appointed will assist the Tuberculosis Officer, and, when necessary, carry out other duties in the Public Health Department under the direction of the Medical Officer of Health, and devote his whole time to the services of the Council.

Applicants should have:

(1) At least three years' experience in the practice of his profession; (2) spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as a resident officer in charge of beds occupied by general medical and surgical cases; and (3) received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

A Diploma in Public Health *is desirable.*

The commencing salary will be at the rate of £600 per annum, rising by four annual increments of £25 to £700 per annum.

The successful candidate will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Forms of application may be obtained from my office, and must be returned, together with a letter of application and copies of three recent testimonials, in envelope endorsed "Male Assistant Medical Officer of Health," not later than Friday, February 27th instant.

Canvassing members or officers of the Council, in any form, will disqualify.

Council Offices, H. E. DENNIS,
Poplar, E.14. Town Clerk.
February 10th, 1931.

Kent County Mental Hospital.

MAIDSTONE.

ASSISTANT MEDICAL OFFICER (male) required. Commencing salary, inclusive of emoluments, £509 per annum, rising to £609 per annum. Excellent facilities for attending lectures for the Diploma in Psychological Medicine, and an additional £50 per annum for that *Diploma.*

The appointment is pensionable under the Asylums Officers Superannuation Act, 1909.

Candidates must be fully qualified, single, and not more than 30 years of age.

Applications, giving full particulars, with *copies of three recent* testimonials, and endorsed "A.M.O." on envelope, should be sent to the Medical Superintendent of the Hospital at an early date.

City of Bradford.

MUNICIPAL GENERAL HOSPITAL, ST. LUKE'S

HOUSE PHYSICIANS and HOUSE SURGEONS required.

These appointments are for six months, renewable for a further period of six months.

Application forms may be *obtained from the* Medical Officer of Health, Town Hall, Bradford, *and should* be returned to him not later than February 28th.

Town Hall, N. L. FLEMING,
Bradford. *Town* Clerk.
February 9th, 1931.

Scunthorpe and District War MEMORIAL HOSPITAL.

Applications are invited for the post of a Second Resident (male) as HOUSE PHYSICIAN, to take up *duties about* the end of March. Salary at the rate of £150 per annum, *with* board, residence, and laundry. Candidates, who must possess registered qualifications, should forward *applications*, stating age, nationality, etc., together with copies of recent testimonials, to the *undersigned* not later than Saturday, February 28th.

ARTHUR E. MAW, Secretary.

Aberdeen Royal Infirmary.

The Board of Directors invite applications for the [illegible] ASSISTANT MEDICAL [illegible]. Six copies should be [illegible] February 18th.

JOHN A. McCONACHIE, Clerk & Acting Treasurer.
230, Union Street,
Aberdeen.
January 30th, 1931.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A RESIDENT MEDICAL SUPERINTENDENT is required on March 9th.

Gentlemen are invited to send in their application to the Secretary, before 12 o'clock on Monday, March 2nd, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for one year, but may be held, subject to re-election, for a period of three years.

Salary £300 per annum, with board-residence in the Hospital, £10 allowance for laundry, and £18 18s. for the purpose of providing a substitute during annual leave.

Candidates must be unmarried and possess a legal qualification to practice, and must have held a responsible Hospital appointment at a General Hospital.

All candidates must be in attendance on Wednesday, March 4th, at 4.45 p.m. precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the Rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES MCKAY,
February, 1931. Secretary.

Hospital Convalescent Home,
SWANLEY, KENT.

There will be a vacancy for a RESIDENT MEDICAL OFFICER (female) on April 1st.

The duration of the appointment is for SIX months, and may be extended for a further SIX months. Salary at the rate of £200, with quarters and full board.

There is a certain amount of active Medical and Surgical work to be undertaken, and candidates should have held a recent resident post in a General Hospital.

Applications, addressed to the Secretary, Hospital Convalescent Home, 18, Walbrook, London E.C.4, should be submitted on or before Friday, February 27th.

CHARLES M. POWER, Secretary.

Ingham Infirmary,
SOUTH SHIELDS. (124 Beds.)

Wanted, HOUSE SURGEON (male). Salary £150 per annum, with residence, board, and washing. No out-visiting. Candidates must hold registered qualifications in Medicine and Surgery. The appointment will be terminable by one month's notice.

Applications, stating age, and accompanied by copies (which will not be returned) of recent testimonials, to be sent to the undersigned, from whom further particulars may be obtained.

JOHN POTTER, Secretary.

Liverpool Hahnemann Hospital,
HOPE STREET.

Wanted, a LOCUM TENENS HOUSE SURGEON to the above Hospital, for one month, possibly longer.

Successful applicant should be able to take up appointment on February 18th.

Salary at the rate of £100 per annum.

Duties include casualties, assisting at operations, and occasional anaesthetics.

Apply, stating age, sex, nationality, and enclosing copies of testimonials, to the Registrar.

Margate and District General
HOSPITAL. (80 Beds.)

Applications are invited for the post of RESIDENT MEDICAL OFFICER (male) to commence duties on March 2nd next. Twelve months' engagement (renewable).

Salary £125 per annum, with board and laundry.

Applications, accompanied by copies of testimonials, should be sent to the Secretary, Medical Committee, at the Hospital, as early as possible.

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2Ca.$

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
2 c.c. size: Boxes of 10 ampoules.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

"Pitibulin" Trade Mark

Denotes Unvarying Pituitary Extract

Conforming to the requirements of the Therapeutic Substances Regulations, 1927, "Pitibulin" is prepared according to the official standards, its activity being expressed in terms of the accepted unit.

"Pitibulin" maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

It has made a reputation among the Profession as the Pituitary Extract which can be relied on in emergency.

"Pitibulin" is supplied in boxes of 6 and 12 ampoules containing 2·5, 5 and 10 units per ampoule.

Literature giving fuller particulars of the therapeutic applications of "Pitibulin" will be sent on request.

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T.M. & Design)

IN BOXES OF 12 "STERULES"

Containing 1, 2, 3, 4, 5, 6, or 10 minima (0.05, 0.1, 0.2, 0.25, 0.3, 0.35, or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving ANGINA PECTORIS, SPASMODIC ASTHMA, MIGRAINE, POST-PARTUM HAEMORRHAGE, HAEMOPTYSIS, to ward off EPILEPTIC ATTACKS, etc., and as an ANTIDOTE to CHLOROFORM. Largely employed in threatened FAINTING and COLLAPSE, and as a RESTORATIVE after GAS in DENTAL OPERATIONS.

Abstracts from the medical literature:

ANGINA PECTORIS: "The best remedy. To lower blood pressure has a more rapid action than any other drug, and is useful in cutting short the paroxysms of pain." —L., ii/05, 325; ii/06, 1335.
"Gave prompt relief in the more pronounced attacks." —B.M.J., ii/06, 304.
"In all spasmodic affections, such as angina pectoris, one of the best remedies."—B.M.J., i/09, 994.
"The nitrites are indispensable."—B.M.J., ii/09, 1122.
"The quickest means of relieving the acute pains." —L., ii/08, 1132.
"Fear of death entirely disappeared."—L., ii/09, 572.
"No drug can compare with Amyl Nitrite."—L., i/09, 240; L., ii/05, 812.

INTRATHORACIC ANEURISM: "For the acute anginal attacks Amyl Nitrite inhalation, followed by internal use of Nitroglycerin or Erythrol Nitrate, is generally efficacious."—L., i/13, 948.

ASTHMA: "In most cases the reduction in blood pressure relieves."—B.M.J., ii/11, 1327.

POST-PARTUM HAEMORRHAGE: "Immediately stopped; no further trouble followed."—B.M.J., ii/06, 1125.

HAEMOPTYSIS: "With few exceptions, promptly effective. Secures peace of mind to sufferers." —L., i/03, 130.
"Some convincing cases in which it saved life." —L., i/07, 939.
"Amyl Nitrite the drug par excellence; acts better the quicker it is used."—Edin. Med. Jl., 1901; L., ii/04, 522, 942, 1446; B.M.J.E., i/06, 79.
"In severe haemoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory."—B.M.J., i/06, 917.

SEA-SICKNESS: Very useful; inhalation repeated every 2 or 3 hours if necessary.

CHLOROFORM SYNCOPE: The quickest means of restoring the heart's action.

PLEASE SPECIFY **MARTINDALE'S AMYL NITRITE "STERULES"**

We also supply other vasodilators, e.g.:

MANNITOL NITRATE TABLETS: 1 gr.

ERYTHROL NITRATE TABLETS: ½, ¼, and 1 gr.

NEW **ANDREWS'** *NEW*

DISEASES OF THE SKIN

HIGH PRAISE from the MEDICAL PRESS

BRITISH MEDICAL JOURNAL

Amid the flood of textbooks of dermatology which have appeared within the last few years that by Dr. G. C. ANDREWS *of New York, "* Diseases of the Skin," *stands out. It is certainly among the best. While it is of ample size adequately to deal with the subject, the author maintains the proper proportions between what it is important for all students and practitioners to know about the essentials of cutaneous medicine and those quaint and interesting rarities which appeal almost exclusively to the specialist, whose attitude towards them often resembles that of the collector of postage stamps towards unique specimens of the philatelic art. Dr. Andrews has brought his account of the subject thoroughly up to date, and in doing so has taken immense pains. There is no better evidence of this than the vast bibliography appended to each chapter, which shows how thoroughly he and his assistants, whose help he generously aknowledges in the preface, have searched the whole of dermatological literature for all that might be useful in this* magnum opus.

A special word of commendation must be accorded to the illustrations, which are both numerous and excellent. In the volume of just over 1,000 pages there are nearly a thousand illustrations, for the most part excellently reproduced from clinical photographs, but there are also many diagrams explaining various points of technique, which will be found most useful. The whole volume is excellently got up, and, considering the amount of matter contained in it, remains moderate in size and easy to handle. We commend it with confidence both to general practitioners and to specialists.

BRITISH JOURNAL OF DERMATOLOGY AND SYPHILIS

There might appear to be very little room for another textbook of skin diseases, but we think that Prof. ANDREWS *has certainly justified the publication of his new volume. The features of the book which appeal to the present reviewer are the very large number of excellent photographs with which it is illustrated, the readable manner in which it is written, the prominence given to treatment, including detailed descriptions of the use of the various forms of radiation therapy (including super-soft or "grenz" X-rays and "surgical" diathermy), and the extensive bibliographies of recent references which conclude each chapter. The type and general get-up of the book are excellent.*

THE LANCET

This new textbook is noteworthy for the wealth and excellence of its photographic records of typical cases, and for that reason especially will rank as a valuable contribution towards the literature of the subject. Its purpose is entirely practical. No less than 130 pages are devoted to the description and treatment of syphilis. Here the reader will derive profit from a study of the clinical illustrations, for examples are included of most of the typical cutaneous manifestations which, as a result of early diagnosis and the rapid effects of salvarsan therapy, can rarely nowadays be demonstrated on patients. Much space is devoted to treatment, and the student should note the line diagrams on p. 725, which purport to explain the occasional extravenous leak after an apparently successful entry of the vein. This section would have been benefited by the inclusion of tabulated systems of routine treatment, with which in other subjects the volume abounds.

There can be no doubt that this book is a contribution of the first rank to the practical aspects of dermatology. It is in part highly technical, and for that reason will attract the trained dermatologist or intending specialist, while the many excellent illustrations will be of great help to the practitioner with dermatological leanings.

INDIAN MEDICAL GAZETTE

We consider that the author has fully carried out the intention that he set out to do when writing this book. He has written this book and embellished it beautifully with photographs, so that it will serve a very useful purpose, and he has kept down the text to reasonable limits and not entered into lengthy and controversial discussions. The book moreover has a very large bibliography which should be valuable to the consultant. There are no coloured illustrations; this enhances the value of the book, as very few coloured plates are really capable of properly depicting these lesions, and by saving expense in this way he has been able to give us this large collection of clinical material. This book on dermatology is one of the best books that has ever been published on the subject.

Octavo volume of 1,095 pages, with 988 illustrations. By GEORGE C. ANDREWS, M.D., Associate Professor of Dermatology, College of Physicians and Surgeons (Columbia University), New York City. Cloth, 55s. net.

ENLARGED (SIXTH) EDITION. *READY MARCH 5th.*

LECTURES ON

DISEASES OF CHILDREN

By ROBERT HUTCHISON, M.D.Edin., F.R.C.P.

Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond Street.

Sixth Edition. Completely revised, with additional Lectures. viii + 476 pages. 104 illustrations. 21s. net.

"As an introduction to the subject, pride of place must be given to Dr. HUTCHISON'S *Lectures on Diseases of Children*. It is written from his experience and touched with his own style and wisdom. It has the advantage of making the subject appear easy—almost too easy. Thus it is brief, easy to read, and the author says what he means."—*From a critical survey of paediatric literature in the* NEWCASTLE MEDICAL JOURNAL.

INSOMNIA
An Outline for the Practitioner

By H. CRICHTON MILLER, M.D., Hon. Director, Tavistock Square Clinic, London. 10s. 6d. net.

"The work is to be cordially recommended. It serves as an admirable introduction and up-to-date review of a difficult subject."—LANCET.

STEADY CONTINUOUS WARMTH APPLIED LOCALLY

To Relieve Rheumatic Pains, Chills, etc., and all such Ailments.

The THERMEGA ELECTRIC PAD takes the place of a hot water bottle in all cases where the local application of heat is prescribed. The heat obtained is instantaneous, constant, and easily regulated as desired. The THERMEGA pad, no larger than an ordinary hot water bottle, is handy and practical for use while travelling. It can be used from any lamp-socket or wall plug at any voltage (100-250). The average cost of current is only 1d. an hour (at 6d. a unit). A special Thermostat control maintains a level temperature and makes overheating impossible.
Ask for demonstration and particulars. Sold by all the big stores, chemists, and electrical dealers, or direct from

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS

arranged for Doctors and Patients.

Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

THE 'STUDA' CHAIR

for

INTESTINAL LAVAGE

The latest and most hygienic method of thoroughly cleansing the lower portion of the alimentary tract.

It exercises and re-educates the muscles of defaecation.

It is unattended by risk, and simple to administer. There is absolutely no odour.

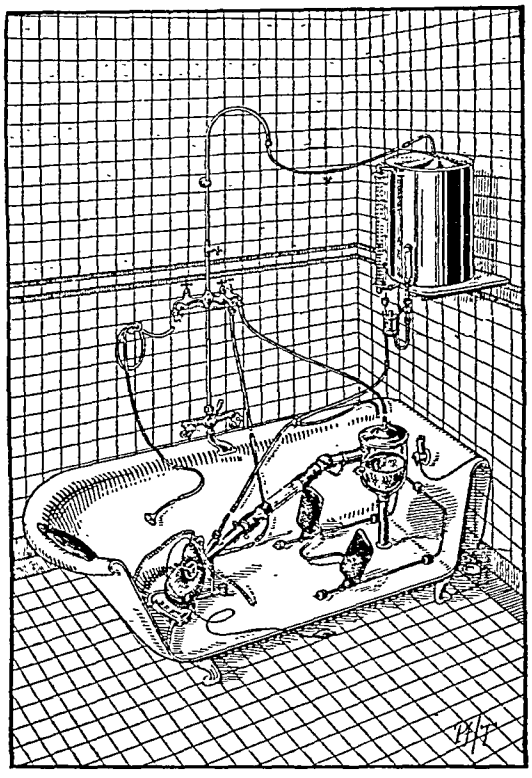
This method obviates undressing and is especially valuable in private practice.

THE 'SUDA' BATH

for

SUBAQUEOUS INTESTINAL LAVAGE

The hydrostatic pressure of the bath counteracts the internal pressure of the irrigating fluid, enabling the treatment to be given without any distension or discomfort. It is simple in operation and exceedingly efficacious.



INDICATIONS FOR TREATMENT.

Constipation (atonic and spastic); Catarrhal Colitis (chronic); Pyelitis and Cystitis (acute and chronic); Removal of ureteric calculi (as revealed by radiograms); Dysentery and Sprue; Cholecystitis; Dyspepsia; Chronic Auto-intoxication; certain metabolic disorders; Vaginitis and Leucorrhoea; Menstrual disorders associated with constipation; in surgical cases preparatory to X-ray examination or abdominal operation; certain chronic eye diseases; certain skin disorders, such as urticaria and serum rashes, etc.

These baths are made abroad and for some years have been successfully used on the Continent in the treatment of the above.

The Collection of Overdue Accounts

WITHOUT OFFENCE

MEMBER'S STATEMENT:

Devon, 5/12/30.

Dear Sir,

Thanks for cheque received yesterday.

I should like to say how very pleased I am with the results of your endeavours to collect my outstanding accounts.

You have certainly been successful in obtaining payment of numerous accounts, to collect which all my previous efforts have been of no avail.

In view of the prevailing colossal unemployment and money-shortage, I think the results reflect the very greatest credit on you and your obviously very capable staff.

Yours faithfully,

THE BULK OF THE ACCOUNTS REFERRED TO IN THE ABOVE TESTIMONIAL WERE OVER SIX YEARS OLD.

Your visiting card marked "B" in an envelope will produce our Prospectus.

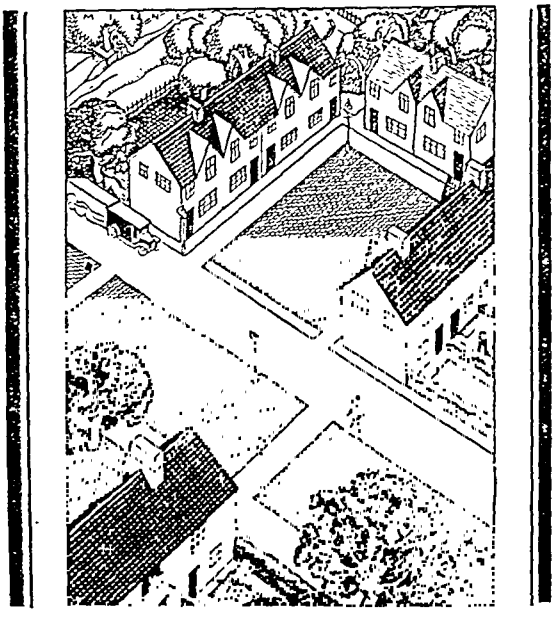
THE LATEST . . . .

NEW HOUSING ESTATES HAVE GAS FOR WATER HEATING



What method of water heating is most up-to-date—best suited to serve your home? The question is answered by the following facts. In nine new housing estates in the area of one gas company alone there are over 5,000 houses and over 500 flats. **All are having gas for water heating.** Gas to give really hot water for every need. Gas to save labour, cut out delays, banish uncertainty. There is a modern gas water heater to suit every type of dwelling.

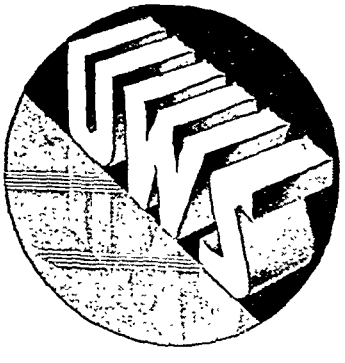
SAFE

THE MOST SATISFACTORY METHOD OF ENSURING A SOFT WATER SUPPLY



Special Booklet Sent Free on Request
"Soft Water in the Home," an illustrated sixty-four page booklet, will gladly be sent to any doctor upon request.

It is a fact of considerable significance that 'Permutit' Water Softening Plants are to-day to be found in over 15,000 homes, and in the leading hospitals, clubs and hotels. No chemicals are used in the 'Permutit' System. This plant provides a soft water which is healthful and palatable to drink, at a moderate initial outlay and an infinitesimal running cost. The plant can be fitted without any alteration to existing arrangements.

UNITED WATER SOFTENERS LTD., ALDWYCH HOUSE, LONDON, W.C.2

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Write for samples and literature to

CREOLIN

(MEDICAL)

Indicated for Use in Varicose Ulcers

CASE REPORTS have shown Creolin to be of marked value as a dressing for varicose ulcers. Whilst displaying adequate germicidal properties Creolin at the same time exerts a powerful stimulating action which induces regeneration of the surrounding tissues. The Creolin dressing is best applied by steeping ordinary surgeon's lint in a dilution of 1 part of Creolin to 300 parts of water. Creolin is a *Liquid Antisepticus* of high germicidal strength combined with low toxicity prepared from highly refined coal tar oils: R.W. co-efficient 18-20.

Testing samples and full particulars sent on application to :—

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905)

Local Anæsthesia in Surgical Practice

EXCISION OF LARYNGEAL POLYPI.

Typical Case.

C. H., female, aged 23 years.

Diagnosis: Laryngeal polypi; tracheotomy.

Operation: Laryngotomy, excision of polypi, laryngectomy.

Anaesthesia: Local infiltration block.

First Operation: Classical infiltration block was made. Larynx was opened in the mid-line in front and a number of polypi removed, using scissors, curette, and cautery. A rubber tube was placed in the larynx and allowed to remain. The incision was closed with drainage. The patient had relief for some time and could even breathe through the normal channels, but within three months the granulation-like masses began to appear once more about the tracheal opening and laryngectomy was decided upon.

Second Operation:

Anaesthesia: A wide infiltration was made, using 90 c.c. of a 0.5 per cent. Novocain-Adrenaline solution. The incision was made and the trachea divided just above the original tracheotomy wound. 10 cm. of the anterior wall of the oesophagus was removed with the larynx. A considerable portion of the thyroid gland was also removed with the mass. The wound was drained extensively, the skin being closed with silkworm sutures. The patient's pulse and colour did not change during operation. The anaesthesia was ideal. This patient has remained well to date. —EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

MONSOL BRAND

MEDICATED SOAP

The importance in Medical practice, and particularly in Midwifery, of sterilizing the hands in order to prevent extrinsic infection has been recently stressed, and it has been shown that washing the hands with a good soap, followed by immersion in a non-irritant but powerful germicide, such as Monsol Liquid, is one of the best means of obtaining sterility.

Monsol Medicated Soap contains 5% of the active principle of Monsol, the germicide which has such a powerful selective action on streptococci, and is therefore powerfully antiseptic. Owing to its absolutely neutral soap base, however, Monsol Medicated Soap does not roughen the hands but keeps even the most delicate skin soft and supple.

8d. per tablet from Chemists everywhere.

MONSOL IS THE SAFE GERMICIDE.

Monsol Liquid— the powerful safe germicide.

Monsol Capsules— keratin-coated, for intestinal disinfection.

When children have *coryza* watch the middle ear

MOST cases of otitis media in children result from extension of a common cold or the coryza associated with influenza or the exanthemata. Unless the primary inflammation in the rhinopharynx is treated vigorously, there is always the danger that the infection may travel through the Eustachian tube and into the middle ear cavity.

Pediatrists and otologists alike urge the necessity of watching the middle ear in all cases of coryza in children. By advising frequent nasal instillations of a light oily solution containing menthol, eucalyptol, camphor and chlorbutol—Mistol—it is believed that many cases of otitis media can be prevented or even checked in their beginning.

The use of Mistol is effective treatment for all conditions of nasal congestion. Its anticongestive and stimulating ingredients are contained in a light oil possessing the most favourable properties for spreading on and clinging to the nasal mucosa, so that the preparation reaches every part and is not readily washed away by accumulated secretions.

Mistol assures greater comfort for little coryza patients and also protection for their ears. It may be diluted one-half with Nujol, for infants, and proportionately for children

WHEN THE PATIENT'S RECOVERY IS HAMPERED BY ANOREXIA . . .

these essences supply stimulus and energy without strain to the digestive system . . .

BECAUSE they are suave and non-irritant in action; because recent scientific tests have shown that they can be assimilated by the digestive organs forty minutes quicker than ordinary foods and without the formation of any residue, Brand's Essences of Beef or Chicken have come to be a preferred invalid food.

99 out of every 100 doctors, recently interviewed, recommend them in cases of intestinal disturbances, in states of exhaustion, in specific fevers, in all disorders associated with pyrexia, and before and after operations.

To-day doctors everywhere are finding these Essences indispensable in the post-influenzal state because they supply energy quickly and prepare the system to accept a more solid diet.

Brand's Essences of Beef or Chicken are prepared by an exclusive process from the finest freshly killed English meats without the addition of colouring matter or preservatives. Patients welcome them because they are delicious to taste and easy to swallow.

Samples will be gladly sent on receipt of a professional card.

REGETHERM POULTICE

CLEAN & CONVENIENT IN USE

More certain in action than the old-fashioned poultice

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

OVALTINE

FOR THE AGED

"Ovaltine" is delicious sustenance for old people. It sustains life ideally by giving tone to the tissues and promoting the healthy activity of the bodily functions.

"Ovaltine" provides complete nourishment in easily assimilable form. Its use greatly increases the nourishing value of other foods. The digestibility of milk, for instance, so largely used in old age, is increased two-fold by adding "Ovaltine" to it, while the starch in the cereals is converted into easily assimilated malt sugar by the enzyme diastase which "Ovaltine" contains in abundance.

"Ovaltine" is purin-free. Its use, therefore, neither aggravates, nor favours the accumulation of uric acid in the system, nor leads to kidney disorder or gout. The tendency to constipation, so common in old age, is avoided by the use of "Ovaltine."

"Ovaltine" replaces to great advantage the usual meal-time beverages, tea and coffee, which are valueless as sources of nourishment and often contraindicated in senility.

A liberal supply for clinical trial sent free on request.

Bismuth-Formic-Iodide Compound

Mulford B-F-I

Supplied in 2 sizes in sprinkler-top tins.

Bismuth-Formic-Iodide Compound, now well known as "B-F-I", is a medicated dusting powder possessing soothing, astringent and antipruritic properties. It is a safe, dry dressing that promotes healing and has been widely used for thirty years by physicians and in hospitals.

B-F-I has the capacity for absorbing fluid from the surface, thereby exerting a drying action. It does not cake or form hard crusts, which would only add to the irritation. B-F-I is, therefore, the ideal dusting powder for use wherever excoriation and a weeping surface occurs.

This compound has been found very satisfactory and effective in treating superficial wounds, eczema, impetigo, pemphigus, ulcers, burns, abscesses, vaccination area, bed or fever sores, chafing, abrasions and similar skin irritations.

ESSENCE of RENNET

CONCENTRATED (BENGER).

(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding. As it is concentrated it is much quicker in its effect than most other preparations of Rennet. Whey prepared with Benger's Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc.; it can be employed with confidence and will yield good results. Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles.
Larger sizes for hospitals, etc., use.

LIQUOR PEPTICUS

(BENGER).

"A digestive agent of extraordinary power."
Sir William Roberts, M.D., F.R.S.

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods.

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone. Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected.

In 4, 8 and 16-oz. bottles.
Prices: 3/6, 6/6 and 12/6.

An Address
ON THE
DOMAIN OF ORTHOPAEDIC SURGERY*

BY
SIR ROBERT JONES, BART., K.B.E., C.B.
F.R.C.S.

It is not my intention to trace this special branch of medicine from earliest times—although such an exercise must have a chastening effect. Our very remote forefathers had philosophical minds, and often practical vision. When, with all the air of a discoverer, we descant upon the value of the sun and open-air hospitals it is a little humiliating to find that the followers of Aesculapius built a temple of healing to the honour of their master, and that the design of the open-air ward was almost identical with our most recent buildings, with free access to sun and air. I wrote an article some years ago on the conservative treatment of club-foot. It might have been copied from Hippocrates, who, with a wealth of detail, had anticipated all I had to say. When we realize the magnitude of this supreme ancient we must feel humble. He enriched surgery in all its branches; but we shall best remember him as a pioneer of extension in the treatment of fractures, as a teacher of passive hyperaemia, as an authority on congenital dislocation of the hip, and on the correction of club-foot—and all this 400 years before Christ.

Some years ago I was engaged as a witness in a medico-legal case. One of the issues referred to the method of reduction which should be employed in a case of dislocation of the head of the humerus with fracture of the surgical neck. Many distinguished surgeons in 1906 did not know of such an injury. They were much astonished to hear that fifty years before the Christian era Pasicrates (quoted by Malgaigne), in describing the injury, stated that he preferred to reduce the dislocation and then to allow union of the humerus. Aristion, on the contrary, endeavoured so to arrange traction that it would act upon both head and shaft simultaneously. Heliodorus supported the contention of Pasicrates. It is of profound interest to realize that in olden times, just as to-day, schools existed, one in favour of immediate reduction and the other in favour of allowing the shaft to unite before dealing with the displaced humeral head; and so it is always.

THE GROWTH OF ORTHOPAEDIC SCIENCE

The term "orthopaedic" was first used by the distinguished Nicholas Andry (1650–1742), professor of medicine of the University of Paris. He wrote an interesting book on the prevention of deformities, and was a great apostle of posture and body mechanics, a branch of work which has been so enriched to-day by Joel Goldthwait of Boston. It is not a satisfactory term, but so far, out of the many suggested, none accurately connotes the group of cases it is supposed to cover. We must, however, come to some clear understanding as to what the definition includes. There was a time when orthopaedic surgery included a comparatively small group of cases. Lateral curvature, flat feet, rachitic distortions, club feet, and a few other congenital conditions represented the list. Apart from tenotomies and an occasional osteotomy, no other operations were indicated. The use of the knife was almost a reproach, and only followed a failure in mechanical effort. How different it is to-day, when some of the most difficult operations in the domain of surgery are included under the definition "orthopaedic"! During the great war I had to direct—on behalf of the British Government—what was known as military orthopaedic surgery, and this involved a statement of what groups of cases ought to be included under the term.

This definition developed into:

1. Fractures—recent, malunited, and ununited.
2. Deformities of the extremities and spine.
3. Diseases, derangements, and disabilities of the joints, including the spine.
4. Injuries of peripheral nerves.

It purposely covered a very large area of surgery, and could only make an appeal to the highest type of young surgeon, as it required an advanced standard of training and exceptional ability. Unless this broad definition were substantially agreed to, advance would be checked and a lower standard of orthopaedic surgery would inevitably arise. We must not recognize as an orthopaedic surgeon anyone who is unable to hold his own in any procedure—operative or otherwise—which his art requires of him. In certain countries orthopaedic surgeons confine their specialty to children. In England we always include the adult in our definition. The same principles applicable to the treatment of the child are also applicable to the adult, and age limit seems to us to be an artificial boundary line.

This war-time definition is now accepted in Great Britain as appropriate in civil life, and no difficulties arise. At first it was felt to include too much, and the surgeon who had not specialized feared a depletion of his teaching material. Once it was understood, however, that it was the orthopaedic surgeon alone who had limitations placed upon him, and that the general surgeon was not limited in his scope by a definition of any sort, all difficulties disappeared. At the outbreak of war the field of orthopaedic surgery was limited to a handful of specialists; where they were not available the cases were often treated by surgeons—not especially interested—in hospitals inefficiently equipped. There was quite inadequate accommodation for prolonged treatment, and no immediate prospect of engaging on a national campaign on the lines of prevention, early discovery, treatment, and after-care. The heavy casualties of 1914 onwards brought appalling facts directly to everyone. The treatment of fractures at the front, because of the conditions, resulted in a high mortality. There was no proper provision at home for the long-treatment essential in certain crippling conditions beyond the general hospitals, already crowded, and in which evacuation had to be rapid. Consequently in both these instances patients either died in the war area or, being evacuated from the hospitals too soon, relapsed and developed permanent deformities. The solution of these problems, which in peace time would have been slow, became so vital and urgent during the war that within a short time the rapid advance of the orthopaedic surgeon was assured. What might have taken a quarter of a century was accomplished in three years. At the front it was decided that casualties within the recognized definition of orthopaedic, as passed by the War Office, should be grouped in orthopaedic centres on their arrival home. In Great Britain centres for proper orthopaedic treatment were accordingly organized, and specially equipped and staffed hospitals for the treatment of fractures were started at the front. The daily spectacle of deformity brought an entirely new and universal sense of the pitiful case of the cripple. A severe counterpoise to the traditional spirit of indifference was produced in all sections of society by the sight of their own flesh and blood stricken with deformity. The contrast was two-edged. The shrinking from the cripple diminished, but inversely the cripple saw that deformity held something which might even prove heroic. That was the psychological contribution of the war towards deformity. But the common experience of complete recovery of function produced a profound realization of the cripple as made, not born, and also as curable. Such an impression so universally received wrought an immense change.

* Presidential address to the International Society of Orthopaedic Surgery, Paris, October, 1930.

THE SCOPE OF ORTHOPAEDICS

It is to the lesson of the war that we owe the wider sense of the importance of adequate means of cure. Out of that profound shattering experience has come the practice in time of peace. The orthopaedic centres were evidence of a system of handling orthopaedic cases, which has been followed since the military beds were evacuated. The temporary necessities of war thus became the permanent accessories of peace. But the war contributed more than hospitals. It formed a training ground of a large number of specialists whose influence was henceforth to compose the wonderful chapter of organization which is now rapidly taking place. In a few years orthopaedic surgery passed from a small branch—with vaguely defined boundaries—into a very comprehensive sphere. Nurses trained in the military orthopaedic centres had learned the lessons that they continued to practise with the crippled in times of peace. Another signal service rendered by war was a thorough understanding and mutual appreciation between those surgeons of our own specialty and surgeons whose work had mainly been carried on in other departments. I think I am correct in saying that only very friendly feelings exist to-day between the so-called general surgeon and the orthopaedic surgeon. In proof of this the Association of British Surgeons and the British Orthopaedic Association have on two occasions selected the same president. This feeling of comradeship and complete understanding should be encouraged; it is a great asset to future progress.

An important lesson learned during the war was the psychological and physical value of work. It was a common thing in our hospitals to find our men attending the various departments for electricity or massage and for the rest of the day sitting nursing their arms or legs. The atmosphere was one of apathy and discontent. We therefore introduced curative workshops there. They proved invaluable as an aid in the recovery of both mind and body. They acted *directly* when the work done gave exercise to the injured limb, and were employed in restoring co-ordinate movements; for instance, a screw-driver was used to supinate the arm and a saw to exercise the shoulder. The *indirect* method was equally productive; a man with a stiff ankle was set to planing, and as he became interested in the work he unconsciously used the ankle. Productive work has a human interest completely absent in mechanical contrivances, such as Zander's apparatus. These methods developed during the war are now part of standardized orthopaedic equipment. They are employed in a scheme of vocational treatment as well as training.

THE SUCCESSFUL ORTHOPAEDIC SURGEON

Most of us have responsibilities to fulfil in the matter of surgical education, and I hope we are all agreed that, before specializing, every surgeon must have a sound practical training in general surgery. An ideal specialist is the general surgeon who concentrates upon a special branch of his art, and not he who becomes a specialist with but little knowledge of surgery as a whole. Most of our French colleagues, who have done so much to advance orthopaedic surgery, still retain their title of general surgeon and practise other branches of their profession. Some of the greatest advances in bone surgery have been made by the general surgeon—for example, Ollier of Lyons and Macewen of Glasgow. There is little in a name. A surgeon is judged good or bad from an orthopaedic point of view by the results of his efforts to correct disability, and not by what he calls himself. His surgery is based on the recognition of definite principles of treatment which lead to the restoration of function—not merely to the correction of deformity. It strives for function rather than for form, but it is more content if it can secure excellence in both. It is conservative and constructive, but it desires to take the most direct road to function—be it by knife, by hand, or by mechanical device. General surgery and orthopaedic surgery should never be divorced. They should move hand in hand to their mutual advantage. Great as our surgical triumphs have been in the past we realize we are only just emerging from darkness. The future is full of promise; its many and intricate problems will not be beyond our power to solve, and we must therefore welcome among us the young, well-trained, and flexible mind, however revolutionary, in order to give us food for reflection and interest in our proceedings.

In my own career I have derived my greatest inspiration from a friendly and close association with the younger generation, especially those who are but little influenced by tradition. They often correct or modify our sometimes crusted views, or by clash of intellect encourage introspection and force us to revise our premisses. Often they merely strengthen us in our views. Truth never shines so brightly as when contrasted with error. As leaders in orthopaedic surgery we should endeavour by every available means to eradicate those diseases which give rise to deformity. It is our duty to ourselves and to humanity. Leaders in a preventive crusade are a greater national asset than mere masters of surgical technique. And what a glorious work! It spreads a spirit of sacrifice and binds together in comradeship with us the official mind, the nurses, and countless voluntary lay workers.

Take, for instance, two diseases—tuberculosis and rickets—which are roughly responsible for half of our cripples. Largely owing to recent research we have sufficient evidence to enable us to state with authority that rickets is wholly preventable. The tragic supply of material in Vienna and elsewhere, as the result of the great war, has furnished us with heartrending evidence, which should move the nations to concerted action. In such noble work our profession should take the lead. We know enough now about tuberculosis to enable us to predict that within a generation it could be stamped out if concerted action were taken. Dirty milk and personal contact are our main enemies, and our objective must be to conquer them. Much is being done, but not nearly enough, to ensure a clean milk supply for our children. We must remember the chain is not stronger than its weakest link, and disease will continue to spread unless the bacillus is absent from all milk or destroyed before milk is supplied to the child. This cannot be effected by voluntary agency alone. The crusade should be directed to the extermination of the disease in cattle, over 20 per cent. of which are infected in Great Britain. When we deal with the human bacillus we ought to be able to evolve a barrier against contact between a child and an infective tuberculous patient. There are difficulties, but they should not prove insuperable. We can make a good beginning by preventing that common tragedy—the evacuation of patients from our sanatoriums who are sent out to die in their homes and, in consequence, spread infection among their families. The human bacillus could be largely eliminated if the authorities insisted upon the proper care and isolation of the consumptive. In Great Britain alone 50,000 die every year from tuberculosis.

ROUTINE AND TREATMENT

We are all anxious, for reasons which are obvious, to have our cases brought to us early, and each nation doubtless has its own methods of securing this. In England —recognizing the evils of foul air, late access, and want of continuity of treatment—we are building a chain of open-air orthopaedic hospitals in various parts of the country, staffed by surgeons and nurses with special orthopaedic training. These hospitals are definitely country hospitals with open-air wards. We recognize, especially

in the care of crippled children, that fresh air and sunlight form an essential basis for treatment. We can safely prophesy that the time will soon come when the town hospital for children will be looked upon as an anachronism. These country hospitals are responsible for the treatment, education, and training of cripples drawn from large adjacent areas. Around the hospital are grouped after-care clinics to which children are brought after being evacuated from the hospital beds, while other cases are seen which require admission for operation or prolonged treatment. These clinics, with their nurses, are periodically visited by surgeons from the hospital, and in this way continuity of treatment is assured and relapse prevented. This network of clinics has resulted in a marked diminution of those gross deformities which are caused by neglect. We hope before very long to see this scheme functioning over all parts of the British Isles.

Despite all that can be done for children by preventive methods we can never hope to be without the cripple problem. The menace of transport is ever increasing, while there is but little corresponding expansion in hospital accommodation. The adult industrial cripple has been neglected in England until lately. Other countries, notably America, are alive to the importance of this problem. There, schemes for rehabilitation are quickly developing. The Federal Board of the United States shows that, up to 1926, 24,000 disabled persons had been restored to work at an average cost of £50 per head. In America alone 84,000 are disabled vocationally every year. This great work relieves the State of a heavy financial burden, apart from the moral aspect of the problem. It is essentially humane and economical.

While we are all deeply interested in the work of our own nation we are very apt to be ignorant of the activities of our neighbours. Nothing can prove of greater value than international meetings in familiarizing us with the activities in which we are interested all the world over. A too rigid nationalism has its grave defects. We are all the better for early access to the literature and work of the several countries, and this is especially so in the cause of the cripple. Brackett of Boston has suggested that there should be a central bureau of information at Geneva, attached to the League of Nations. It should act as a centre for collecting and distributing information regarding cripples in all civilized countries. It should cover preventive treatment and training, and should include methods of dealing with those injured in industry. Such a source of information would be a great service to all of us. It would unite the nations in a common quest.

A CASE OF PITUITARY TUMOUR

BY

C. C. ELLIOTT, M.D., B.S.

SURGEON, SOMERSET HOSPITAL, CAPETOWN, AND LECTURER IN CLINICAL SURGERY, UNIVERSITY OF CAPETOWN

AND

DAVID P. MARAIS, M.D., F.R.C.P.ED.

PHYSICIAN, SOMERSET HOSPITAL, CAPETOWN, AND LECTURER IN CLINICAL MEDICINE, UNIVERSITY OF CAPETOWN

The subject of this report is a professional man now 50 years of age. He was first seen about seven years ago by one of us (D. P. M.) in consultation with his family attendant. The particular interest in the case lies, in the first place, in the curious onset, and secondly, in the pathological cause, the removal of which eliminated in large part the original symptoms.

SIGNS AND SYMPTOMS

The earliest symptoms arose some twelve months prior to the consultation. The patient's partner had noticed a marked slacking-off in his work. Although he attended office punctually and regularly he accomplished very little real work, spending most of his time behind closed doors, writing voluminously, and destroying at the end of the day the results of all his labour. He took little interest in his profession, but when asked his opinion seemed as alert and as sound as usual. On rare occasions a letter missed destruction, and several were gradually collected. In one of these the patient styled himself a knight, and wrote about the millions he was investing. The theme was usually suggested by a business letter or a consultation. Thus, following a consultation on mining matters, his subsequent letters dilated upon the millions paid by this mine, all earned by himself; after a professional conversation about shipping he wrote to his son, still a schoolboy, about his yacht, giving it the name of a liner previously discussed, and describing his wanderings across the Seven Seas. In other respects—in conversation, intelligence, and in conduct—he appeared to be his normal self.

When first examined the patient was a heavily built man, 71¼ inches in height and weighing 203 lb., with large features and a strikingly pallid complexion. The facial characteristics were somewhat prominent supra-orbital ridges and malar eminences, and a heavy lower jaw; there was also some puffiness below the eyes. The hands were large, and showed distinct thickening of the skin—a "solid oedema." The skin of the trunk was smooth and very pallid. There was general loss of hair, the pubic hair being scanty and resembling in its distribution that of the female. The penis was small, as were the testes, which were insensitive to pressure. The patient complained of loss of sexual desire and admitted impotence. Generally the trunk indicated the adipose appearance associated with a pituitary dystrophy. Other symptoms —for example, headache, vomiting, etc.—were strikingly absent. The patient, in fact, had no complaints to make, and only admitted, rather shamefacedly, the indulgence of "day-dreams," as he called them, when he composed his letters.

A systematic examination elicited the following facts. The cardio-vascular system showed little abnormality. Blood pressure was 130/80; pulse rate was 70. Examination of the heart revealed no enlargement or degenerative changes. The blood picture indicated a mild grade of anaemia—4,950,000 red cells per c.mm., and 78 per cent. haemoglobin. A census showed cells of normal size and staining capacity, and a slight relative lymphocytosis.

Occasionally, at irregular intervals, the urine contained a small amount of sugar and a trace of albumin (salicylsulphonic acid test). A glucose tolerance test gave fairly

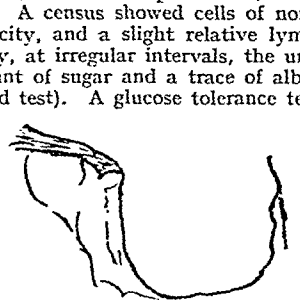

FIG. 1.—Tracing of sella turcica (26 × 25 mm.).

normal values, fasting sugar in one test being 0.0665 mg. per cent. After 50 grams of glucose had been taken the percentages of sugar recorded half-hourly were: 0.0915, 0.125, 0.093, 0.073, 0.0592, with a urine specific gravity of 1032; yet no sugar was excreted. A urea concentration test indicated 3.7 per cent. of urea after the first hour, and 4.1 per cent. after the second hour. The deposit contained no cells or casts, only an excess of phosphates being present. Examination of the eyes disclosed a restriction of the fields of vision. A full examination was made by Dr. A. W. Sichel, whose report is appended. An *x*-ray examination of the skull by Dr. van Rooyen indicated clearly a very much enlarged pituitary fossa measuring 26 by 25 mm. (normal 13 by 8 mm.) (Fig. 1).

The diagnosis arrived at was that of a tumour or enlargement of the pituitary body causing increase in size of the sella turcica and pressure symptoms on the right optic chiasma affecting particularly the right optic tract. The patient was then placed in the hands of Dr. C. C. Elliott, who decided to operate.

OPERATION

On February 2nd, 1924, an osteoplastic flap was turned down over the right frontal region with its base external. The right lobe was elevated in its dura mater. After identifying the lesser wing of the sphenoid, the optic nerve was traced. The dura mater over the sella was then opened, and a purplish tumour was seen. It was spooned out with a blunt spoon. The sella was deep. The flap was replaced without drainage. The patient was conscious the same evening.

PROGRESS NOTES

There was at first paresis of the right internal rectus, and partial ptosis of the right eyelid. The patient was blind in the right eye, but could see with the left. The paresis of the right rectus and eyelid soon improved. During the first few days he was restless and irritable, but rapidly became normal. The wound healed by first intention. On February 20th the patient could read with the left eye. In May he reported that he could do three hours' work a day, walk two miles, see clearly with the left eye, and that he had no "day-dreams."

Having examined him in January, 1925, Dr. Sichel reported that the vision of the left eye was better, although the fields were the same as before. The patient said he had "day-dreams" when he was pressed with work. The hair of the head was much thicker and more luxuriant. He was still impotent. He worked full time at his office. In the interval he had taken pituitary extract regularly. Drs. Marais and Kooy saw him and recommended mixed endocrines.

In 1927 Dr. Sichel reported that the vision was not so acute and that the fields were slightly more constricted. The patient still had occasional "day-dreams." The pubic hair had partly grown, not the axillary, but there was some hair on the arms and the hands. He had still no libido. He could perform all his work.

In 1930 the patient was examined at his home. He still managed his office, but had "day-dreams" when fatigued. There were no further changes in acuity of vision, nor any other symptoms.

COMMENTARY

We have reported this case, having followed it up for over six years after operation. We operated at the right side, because, though the field of vision was more open on that side, the onset of complete blindness was more advanced in that eye, and therefore operative injury to the right optic nerve would not have been so serious. The perimeter charts demonstrate how the field cleared on the other side. Apart from the curious fantasy symptoms, the patient has led a normal and useful life since the operation. Whether the mental symptoms are due to an endocrine defect we do not know.

PROFESSOR BARTLETT'S REPORT

Naked-eye examination of the pituitary tumour showed some fragments of soft friable tissue of a brownish colour. Microscopical examination revealed acinar and intra-acinar papillary, polygonal-celled carcinoma of anterior lobe of the pituitary gland. The cells forming the growth were epithelial, obviously arising from the acinar epithelium. The appearance was very atypical: the acini were much larger than normal, and some of them were dilated, but filled by intra-acinar papillary growth. The cells which filled the acini and covered the papillae were large and polygonal in shape. The nucleus was large, round, or oval; their protoplasm was abundant, faintly eosinophile, and spongy or vacuolated. Cells containing haemotoxyphil granules were extremely rare, but a careful search revealed a few; these were large and occasionally multinucleate. One of the fragments showed colloid spaces of the pars intermedia; another showed tissues of the anterior lobe; in each case there was invasion by growth. A small portion of brain tissue showed no invasion. Fragments of the capsule showed definite invasion. The growth was of a common "adenocarcinoma" type frequently reported in this situation. As usual, most of the cells were "chromophobic"—that is, they did not show granules. The growth was therefore composed of those cells which proliferate in pregnancy. The benign type of this neoplasm is sometimes found after repeated pregnancies, and generally regresses spontaneously.

DR. SICHEL'S REPORT

The patient was referred to me on January 24th, 1924, by Dr. D. P. Marais for a report on the fundi and visual fields. There was a history of enlargement of sella turcica, as shown by *x*-ray examination, and symptoms of pituitary and thyroid involvement. The patient stated that he had had diplopia since May, 1923, especially when reading.

Vision.—Right eye: with a correcting lens of −0.50 spherical and −0.50 cylindrical, axis 90, fingers were seen at 1 metre. Left eye: with −4.50 spherical and −0.50 cylindrical, axis 90, his vision was 5/36.

Pupils.—Equal in size, sluggish response to light both directly and consensually; no obvious response to convergence.

Fundi.—No definite pallor of discs. Examination complicated owing to presence of myopic coni and greyness of lamina cribrosa. No gross pathological changes in retina or choroid.

Fields.—No central scotoma for colours (Figs. 3 and 4). Central vision of right eye appears to be involved—that is, fixation object comes and goes. Tests for diplopia impossible owing to defective image perception in right eye.

Diagnosis.—Examination indicates pressure in direction of arrow (Fig. 2) involving crossed fibres from left eye

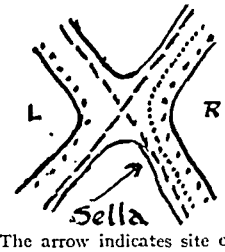

FIG. 2.—The arrow indicates site of pressure.
Crossed fibres: ————————
Uncrossed fibres: - - - - - - - - - - -
Macular fibres: .....

and macular bundle from right eye: uncrossed fibres from right eye not implicated.

Progress Notes.—February 29th, 1924: First examination since operation. Right eye diverges and vision in it is *nil* (no perception of light). Vision left eye with correction = 5/18 partly. Reads J1 with difficulty. Fundi unchanged. See field (Fig. 5). March 5th: Right eye, vision *nil*. Left eye with correction = 5/12 partly. Examination of left visual field by Elliott's scotometer shows sector of blind area extending to about 5 degrees from fixation point. January 5th, 1925: Right eye shows optic atrophy. Left fundus normal. Vision left eye = 5/8 partly. Right eye slightly divergent and has no power to converge. See field (Fig. 6). March 14th, 1927: No further complaint. Has never been able to do much extra reading since operation in spite of improved vision. Vision left eye with correction = 5/12 partly and reads J1 with difficulty, having to make out words one by one. Right pupil reacts very slightly to direct light. Fifth nerves, as indicated by no loss of corneal sensibility, not involved. See field (Fig. 7). October 4th, 1928: Patient advised to return home; he has done more harm to himself by anxiety than can be explained by actual loss of vision. See field (Fig. 8).

MANIPULATIVE REDUCTION OF CRUSH FRACTURES OF THE SPINE*

BY

R. WATSON JONES, M.CH.ORTH., F.R.C.S.ENG.

LECTURER IN ORTHOPAEDIC PATHOLOGY AND CLINICAL ORTHOPAEDICS, LIVERPOOL UNIVERSITY

For at least two thousand years it has been recognized that fractures demand immobilization, and for many hundreds of years methods of reducing fractures have become more and more specialized and more and more successful. It is therefore the more inexplicable that crush fractures of the spine have been neglected, and that an apathy which would have been criticized in the treatment of other injuries has been condoned and even commended. It cannot be said that it is the layman alone who has regarded a broken back as irreparable, and until recent years there appears to have been no systematic attempt to reduce these fractures. The object of this paper is to record—it is believed for the first time—a method of reducing crush fractures of the spine, safe enough and simple enough to be capable of universal application, and of giving successful results in the hands of any practitioner who knows the rudiments of plaster work. It has the value of requiring no anaesthetic, no apparatus, and no skilled assistance, and can be applied as effectively in a private house in the country as in a fully equipped hospital.

RESULTS OF INADEQUATE TREATMENT

The growing risks of industrial life and of life on the highways has led to a remarkable increase in the frequency of this injury. During the last two years I have seen no fewer than sixty-five cases of crush fracture of the spine which have been treated elsewhere by the accepted method of simple recumbency in bed for a few weeks. That these patients are still wandering from surgeon to surgeon and from clinic to clinic is itself evidence that a serious disability usually remains.

The angular deformity of the spine which always appears is often progressive, because there is continued absorption of the unprotected wedge-shaped vertebra. In those cases where, in addition to the crushing of a vertebra, there is forward dislocation of the upper segment, the spine is mechanically unstable, and on several occasions it has been observed that the forward slipping has continued several years after the injury, despite the constant use of a posterior spinal support. But the group of cases which is most important, because, although amenable to successful treatment, it is neglected, is that in which the obvious complication of paraplegia has not arisen, and yet there is an angular kyphotic deformity of greater or less degree. The malalignment of the complex system of spinal joints accounts for the complaint of "weakness of the back," early onset of fatigue after exertion, persistent local aching pain, and sharp pain referred to the chest, abdomen, or lower limbs. It also accounts for the development of osteo-arthritic changes at an unusually early age. These problems are not to be solved by attributing the symptoms to hysteria, by labelling the case "industrial back," and having recourse to county court arbitration. Nor can they be solved by operative fusion of the spine in the late stages. The solution is to treat the case from the outset as a fracture or dislocation in any other region of the body would be treated—namely, by manipulative reduction of the displacement and immobilization until the fracture is consolidated.

* Synopsis read before the annual meeting of the British Orthopaedic Association, London, November 28th, 1930.

RATIONALE OF MANIPULATIVE REDUCTION

We know that the vertebra is crushed by forcible flexion of the spine, and that the kyphotic deformity is one of acute flexion at the level of the injury. It follows that reduction can be effected only by moving the spine in the opposite direction of extension. When the normal limits of hyperextension are reached, weight is taken off the front of the vertebral bodies, the intervertebral spaces are opened anteriorly, the anterior common ligament is put on the stretch, and the tension of the ligament is such that a vertebra crushed into a wedge will be restored to its original shape.

During the last eighteen months several articles have appeared in America describing methods of reduction of compression fractures, but although the methods have been successful in the authors' hands, all of them have been based on manœuvres either too difficult or too dangerous to admit of general application. A general anaesthetic has been regarded as essential, and the operators have insisted on prolonged recumbency after reduction in a plaster bed. The most notable contribution was that of Davis of Erie (Pa.), who described the results in thirteen cases where traction and forcible hyperextension were combined by suspending the anaesthetized patient from the roof of the operating theatre by the heels, in such a way that he was lying face downwards on his upper chest, the lower half of the spine and the lower limbs being in mid-air. A plaster bed in which the patient subsequently lay was made in this position. Herzikoff described a case of reduction in which four strong men had combined to exert traction on the patient's spine. According to one method I saw practised in the United States, after suspending the deeply anaesthetized patient by the Davis method, the operator thrust with the whole of his body weight on the patient's spine "until the bones were felt to crunch."

Such a method is based on an entire misconception of the structure of the vertebral body and of the pathological anatomy of a crush fracture. The cancellous bone of the body of a vertebra is a delicate framework, which rapidly collapses as soon as the enveloping layer of compact bone is fractured. Once the compact layer is broken very little force is necessary to make the vertebra collapse, and an equally small force applied in the opposite direction will open up the cancellous tissue again. Moreover, the interlocking of the segments of a fully extended spine is so close that the trunk above and below the level of fracture provides a pair of unusually powerful levers.

We have, in fact, found in practice that if a patient with a crush fracture of the vertebra, within a few days of the injury, lies prone with hyperextended spine, supported only by his arms at the side of his head and by the front of his thighs and legs, leaving the trunk entirely unsupported, *body weight alone* is sufficient to restore the vertebra to its original shape and give perfect anatomical reduction. Completely successful results have been secured by this very simple method, even ten days after the injury, but the ideal time for reduction is the first day. The method involves no manipulation, no trauma, and no anaesthetic, so that there is no danger of increasing the shock. The shock, in fact, begins to disappear as soon as the plaster is applied, because only then is the patient free from pain, and only then can he be moved in comfort. Not until the plaster is applied is the danger of cord injury avoided, and if there is already paraplegia the only hope of recovery lies in immediate relief of pressure. Moreover, it is the recumbency of the first few days which may precipitate pulmonary congestion and pneumonia, and the sooner it is possible to change the patient's position regularly and frequently the more certainly is pulmonary complication avoided.

METHOD OF REDUCTION

Not only is a general anaesthetic quite unnecessary, but the position required can be maintained much more easily by a conscious than by an anaesthetized patient. Although complaint is made of aching and discomfort in the arms where the weight of the trunk is borne, none of the patients complained of pain in the back, so that we have not thought it necessary to adopt Böhler's suggestion of injecting novocain locally. One-quarter or one-third of a grain of morphine is given half an hour before.

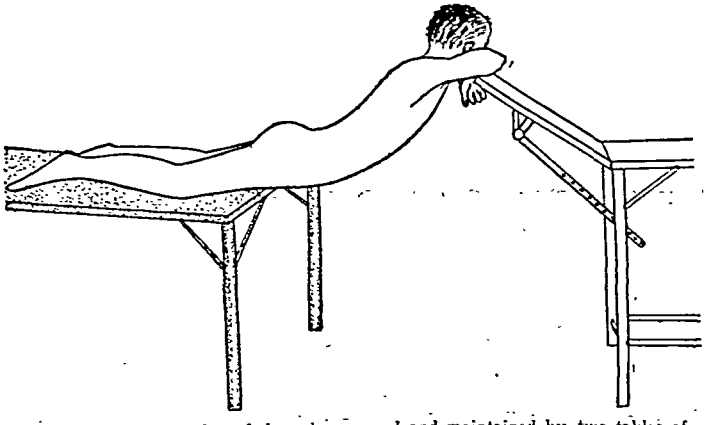

FIG. 1.—Hyperextension of the spine secured and maintained by two tables of different height.

Two tables are arranged end to end, with a space between slightly greater than the length of the patient's trunk. The front table is raised on blocks or chairs so that it is about two feet higher than the other; although not essential, it is an advantage to use an operating table of adjustable height, so that the hyperextension can be attained gradually by screwing up the table after the patient is in position. Throughout treatment, flexion of the spine must be avoided. The patient is therefore lifted *face downwards* on to the lower table, and a double layer of stockinette pulled over the trunk and stitched over the shoulders and beneath the perineum. The spinous processes and the iliac crests may be further protected by small pads of adhesive felt, but it is essential that the plaster should fit very closely; bulky padding with wool or felt is to be avoided. A closely fitting woollen bathing costume is an excellent substitute.

The patient is now assisted into such a position that he is gripping the edge of the higher table with his abducted arms, the head resting on a small pillow. The lower table supports his lower limbs as high as the upper thigh, but between the groins and the neck there is no support. In this position he is unable to prevent his spine from gently sagging into full hyperextension (Fig. 1). The plaster is applied at once, and is well moulded to the curve of the spine, the sacrum, and iliac crests. The rubbing in of layer after layer of plaster gives just sufficient pressure to ensure that the normal limit of hyperextension has been reached; beyond this no manipulation of any sort is employed. The plaster should extend up to the neck, and although it may be cut out below each axilla to allow free arm movement, none must be removed from the front of the thorax (Fig. 2). It extends well over the sacrum and down to the level of the trochanters and symphysis pubis, with a small area cut out over each groin to allow flexion of the hips. If the plaster is a good, closely fitting one it is not necessary, even in lumbar fractures, to include either hip, and we strongly deprecate the suggestion that these patients should remain recumbent in a plaster bed or frame.

AFTER-TREATMENT

As soon as the plaster is dry the patient is encouraged to move about in bed, and is turned frequently to avoid pulmonary congestion. Wasting and hypotonicity of the spinal musculature must be avoided. From the second or third day in uncomplicated cases definite exercises for the erector spinae are practised at regular intervals. The patient should lie prone and lift the head from the bed against resistance. Each lower limb should be lifted with the knee straight by hyperextending the hip. These exercises involve energetic contraction of the erector spinae, and despite the plaster jacket a patient can maintain a better muscular tone in this way than he could if any amount of massage and electrical treatment were possible.

After ten days the patient may get up and walk for increasing intervals. We regard this as a very necessary part of the treatment, not only because it still further assists in maintaining muscular tone, and establishes the free circulation which is essential for rapid union, but because it restores the patient's mentality to normal. The sooner a man is dispossessed of the notion that "his back is broken" and that he "will never walk again," the more certainly is subsequent functional disturbance avoided.

Protection of the vertebra is necessary for four months. If exercises are being constantly practised the plaster should be retained for the whole of this time. After sixteen weeks movements of the spine itself are practised, and if a normal musculature and a normal circulation have been maintained there will be no difficulty in restoring full movement. Manipulation to break down intermuscular adhesions will not, as a rule, be necessary. Within six months he should be capable of resuming his normal occupation.

FIG. 2.—Plaster jacket completed.

RESULTS OF TREATMENT

During a two-year period sixty-five cases of fracture of the vertebral bodies have been seen either privately or in hospital. Manipulative reduction was attempted in seven cases where the injury was of less than one month's duration. In one, of three and a half weeks' duration, paraplegia was present with urinary infection already well established, and the patient died of uraemia four weeks later. The other six men were seen within a few days of the injury, and in each case reduction was completely successful. Anatomical reposition of the compressed vertebra was secured (Figs. 3*a* and 3*b*, and 4*a* and 4*b*), with a normal range of movement. In two cases there was slight ossification of the anterior common ligament with the formation of a symptomless spur, but no osteo-arthritic changes have supervened.

FIRST-AID TREATMENT

All first-aid workers should be taught in the future that a patient with an injured spine must be carried face downwards. No first-aid splintage can be perfectly efficient, and if, as is customary, he is carried by the shoulders and the hips, some degree of sagging between the points of support is almost inevitable. If he is face upwards the spine is flexed, and, however momentary this may be, the deformity must be exaggerated and the risk of injury to the spinal cord greatly increased. If, on the other hand, he is carried face downwards the spine is hyperextended. Not only is no harm done, but it is more than possible that the displacement will be reduced by the time he reaches hospital.

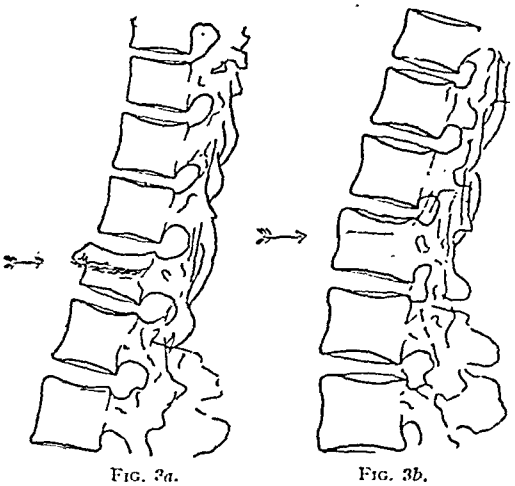

FIG. 3a. FIG. 3b.

FIG. 3a.—Lateral *x*-ray of eight-day-old crush fracture of first lumbar vertebra before reduction. (Case P.P. 1486.)
FIG. 3b.—Lateral *x*-ray of same case as Fig. 3a the day after reduction and plaster.

CONCLUSIONS

The experience of these seven cases has thrown a new light on the condition known as Kümmell's disease of the spine. It has long been recognized that the progressive absorption of the vertebral body which characterizes this disorder is due to trauma, but it has been difficult to explain why the radiogram taken within a short time of the accident has shown no injury, whereas later radiograms have shown very marked absorption. This is now explained, for we have seen that even after a very severe compression simple hyperextension will restore a vertebra so perfectly that in the post-reduction radiogram it is practically impossible to localize the injury. Figure 3b shows a radiogram taken the day after reduction. If in this case there had not been a previous *x*-ray examination, the radiologist would certainly have reported either no bone change or a very trivial injury. Yet Figure 3a, taken twenty-four hours earlier, shows very marked collapse. It is clear that the condition described by Kümmell differs in no respect from any other compression fracture of the spine, except that reduction was spontaneously effected before the first radiogram was taken. When the case with which reduction can be secured is realized, there is no difficulty in recognizing the possibility of spontaneous reduction.

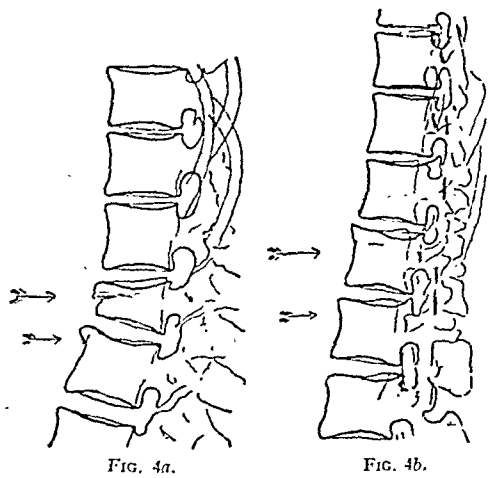

FIG. 4a. FIG. 4b.

FIG. 4a.—Lateral *x*-ray of nine-day-old crush fracture of second lumbar vertebra before reduction. (Case P.P. 1203.)
FIG. 4b.—Lateral *x*-ray of same case as Fig. 4a, showing end-result twelve months after reduction.

The reading of an *x*-ray film of the spine is therefore not to be undertaken lightly. Only the most perfect films can be relied upon, and the slightest sign of injury must be regarded with suspicion. Moreover, the surgeon himself must recognize the possibilities of serious collapse which lie behind apparently insignificant degrees of compression of a vertebra, and such "trivial" injuries must be treated with the respect they deserve.

Summary of Cases of Crush Fracture of the Spine Treated by Reduction and Plaster.

Case No.	Sex	Age	Duration	Localization	Complication	Treatment	Result
P.P. 481	M	33	1 day	12th dorsal	—	Reduction; plaster for 10 weeks	Fracture fully reduced, but some absorption occurred later owing to protection for too short a period. Slight pain. Normal occupa-
P.P. 1203	F	45	9 days	2nd lumbar	—	Reduction; plaster for 4 months	1 5 months.
P.P. 1486	F	59	8 days	1st lumbar	Fractured pelvis	Reduction; plaster	reduction. (Figs. 3a and 3b.)
B.G.H. 1718	M	33	25 days	1st lumbar	Paraplegia; urinary infection	Reduction; plaster	Died 4 weeks later from uraemia
B.G.H. 1744	M	30	5 days	12th dorsal	—	Plaster 3 months; spinal support 6 weeks	Complete recovery. Resumed heavy work in 6 months
L.R.I. 11680	M	23	9 days	1st lumbar	Fracture of tarsus, R. and L.	Plaster and spinal support 6 months	Spine fully recovered. No symptoms
L.R.I. 15146	M	51	1 day	2nd lumbar	Fracture of transverse processes L2 and L3	Plaster 3 months; support 3 months	Perfect result. Drives heavy car all day without symptoms

THE CLINICAL VALUE OF A NEW REFLEX IN CHOREA*

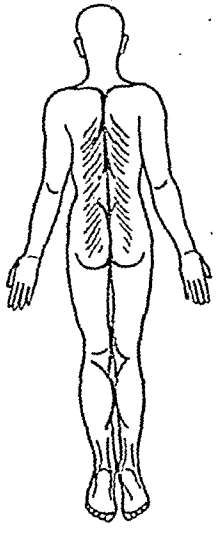
BY

G. ARBOUR STEPHENS, M.D.

CONSULTING CARDIOLOGIST, KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION; SENIOR CONSULTING PHYSICIAN, CARDIGAN AND DISTRICT MEMORIAL HOSPITAL

A boy, aged 9, was sent home from a boarding school because his behaviour was peculiar, and his teachers were unable to manage him. He was brought to me by his mother, who was more concerned about his mentality than about his general health. The school medical officer had noted that his heart was not normal, and for this reason had suggested I should be consulted.

On examination I found his mental condition sound, but sluggish. His heart beat was heaving, and the sounds were abnormal, having a relative value, as estimated by my cardioscope, of 1—¼ instead of 1—1. The boy was restless, and his pupils were widely dilated. His blood pressure by my method was 170/90, the basic pressure being very high. The urine contained no albumin. Over his back, from the third dorsal spine to the buttocks—the shaded area in the figure—there was hyperaesthesia and a marked superficial reflex.



Diagrammatic representation of the dorsal reflex.

It is of importance to note that the parents are butchers, both taking an active part in the shop, and as a consequence the child was somewhat neglected, and had got out of hand. He inherited a strong liking for meat, of which he ate large quantities; he was also fond of condiments. His mother stated that he would eat a pound of sausages at one sitting. One point was that he disliked milk, which contains a high percentage of lime.

THE DORSAL REFLEX

The presence of the dorsal reflex helped me to diagnose without any hesitation that the boy was suffering from chorea. During a recent investigation of this disease the dorsal reflex arrested my attention. The first case in which I observed it was that of a boy, aged 8, who had a red oval patch, about 6 inches long, over the hip-joint on which he had been lying. This patch was hypersensitive, but as the area of this abnormal condition extended higher up the boy's back it was obvious that the redness was due to pressure and not to a trophic lesion. On both sides of the spine hyperaesthesia was found extending as far up as the third dorsal vertebra, and down to and including the area supplied by the second sacral nerve. In addition to hypersensitiveness there was also a marked superficial reflex, the trapezius, latissimus dorsi, and glutei muscles responding readily when the overlying skin was pricked lightly with a pin. The nerve supply of this hypersensitive area is the third to the twelfth dorsal, the lumbar, and the first and second sacral nerves. This reflex can be demonstrated in nearly every child suffering from chorea; it does not seem to be dependent in any way upon heart disturbance, because (1) it occurs in chorea patients whether the heart is affected or not, and (2) it is not found in patients suffering from acute rheumatism with acute carditis.

BASIC PRESSURE AND TOXAEMIA

In the first boy referred to it will be observed especially that the basic pressure was very high. This is a consistent factor in chorea. We define the basic pressure as that pressure left acting on the blood in the brachial artery after the systolic pressure has been stopped by the inflated armlet; my method of estimating it has been previously described.[1] By my method the normal basic pressure is found to be about 50 mm. Hg, but in children suffering from chorea the basic pressure is raised to 70 mm. or upwards. A rise of this sort is due to some toxin probably introduced into the blood. This fact is proved by some experiments I made on men before and after taking glasses of whisky. Furthermore, in spelter furnace-men whose urines contain lead, I have found that the basic pressure rises in a way that seems to correspond with the amount of lead in the urine. The basic pressure can thus be raised by both organic and inorganic poisons, and it is quite justifiable to infer that in chorea this results from a toxaemia.

One effect of a poison on a living cell (such as a white blood corpuscle or an amoeba) is the modification of its surface tension. This is readily demonstrated by adding a trace of chloroform to a slide on which is a living amoeba; the latter takes up the smallest possible space by becoming spherical. When the surface tension is altered, it is found that the osmotic forces are disturbed, and that the intake and output of the corpuscles are greatly modified; in other words, the metabolic processes of the organic unit are completely altered. A particular poison in the blood affects the surface tension of the individual corpuscles, and by so doing produces a metabolic change corresponding exactly to the poison introduced—that is, the antigen is essentially specific. It is important to remember that when the basic pressure is raised, the entrance of the blood into the vasa vasorum becomes more difficult, because the added force tends to compress the mouths of the vasa vasorum, the obstruction being proportional to the increase. Consequently the muscular fibres of the arterial wall are ill-nourished and cannot contract and dilate with a normal response to stimuli. When the arterial wall is affected in this way the supply of blood to the parts or organs is unsatisfactory, functions are seriously disturbed, and, after a period of sufficiently prolonged malnutrition, arteriosclerosis sets in and the condition becomes chronic.

One important point which seems to have been overlooked is that although the basic pressure is taken over the brachial artery, it does not follow that the reading in this part is a figure representative of the basic pressure in the arteries of the lung, heart, brain, or abdominal organs; the basic pressure varies with different parts of the body, whereas the systolic pressure, being that due to the pumping pressure of the heart, must be the same for all parts. The basic pressure is lowest in the lungs and brain, and highest in the coronary vessels, because of the contraction of the powerful heart muscle. It follows, therefore, that with an increased pressure in the coronary arteries the supply of blood to the heart muscles must be unsatisfactory, with the result that the heart muscles contract irregularly and give us the signs we find in toxic conditions of the body. When the amount of blood toxin is considerable, especially in a patient in whom the normal condition of the blood is poor, a slight increase of basic blood pressure will easily bring about some malnutrition of the heart muscles.

I have often pointed out that chorea and acute rheumatism occur in the type of child whose intake of

* A paper read to the Swansea Division of the British Medical Association, December 18th, 1930.

lime-bearing food is low but whose intake of acids is high. The blood of such a child is in a very unstable condition and apt to be upset by the introduction of protein poisons conveyed by the bite of an insect. Proof of this is shown by the early rise of the basic pressure.

BASIC PRESSURE AND CHOREA

It follows from the above statements that in chorea with an increased basic pressure the supply of poor blood to the walls of the cerebral arteries must diminish the blood in the brain. As a result, the brain cells act irregularly and so set up irregular stimuli, producing a corresponding choreic effect on the muscles. This statement is especially applicable to the chorea associated with pregnancy, in which toxic conditions are known to be present in a very pronounced quantity, affecting powerfully both brain and heart.

In order to try to add to the value of the above statements I think it desirable to draw attention to some observations I have made regarding Raynaud's disease. All the cases which I have examined have a relatively high basic blood pressure. This point is important, because if the basic pressure be 50 (which is the normal figure) and if the systolic pressure be only 90 the power to force blood into the vasa vasorum is as difficult as if they were 100 and 190 respectively. My findings in connexion with the inflow of blood into the vasa vasorum and the consequent ill supply of nourishment to the arterial muscular fibres are consistent with the facts put forward by Lewis and Kerr[2] when they state that "undue cooling of the hand failed to bring on an attack" because, as they point out, "the minute vessels of the skin of these patients react, as do those of normal skin, to excessive cold by dilating." In my experience, excessive cold has been sufficiently stimulating to make even these badly nourished arterial walls respond.

The observations of Lewis and Kerr have driven them to the conclusion that there is an abnormality of the vessel wall, and also that the closure of the vessel is not reflex. They therefore confirm my conclusions and, indirectly, my work on the basic blood pressure itself.

It seems to me that one can say that chorea is a sort of Raynaud's disease or "spasm" of the brain arteries, while the cold white fingers of a man with an "alcoholic" nose which is bluish red is also a Raynaud's arterial disturbance. I differ from Lewis and Kerr when they apply the word "spasm" to the state of the vessel in Raynaud's disease, because it suggests a hypercontractability of the muscular fibres of the arterial wall. Such a hypercontractability is not to be expected in a badly nourished muscle, but rather a weakness of its tone. The difference is of great importance. As I have pointed out elsewhere,[3] "To suggest that the diseased muscular fibres of the auricle are capable of developing fresh centres of excitation seems to be contrary to the usual rule regarding dying matter, whereas, on the other hand, the diseased muscular fibres forming the thin wall of the auricle lend themselves to be thrown *passively* into a state of tremor." It is interesting to compare this observation with the action of the heart in acute carditis, in which badly nourished muscular fibres in the wall of the auricle, influenced by raised blood pressure, allow of the onset of a passively produced tremor, usually called "fibrillation."

THE "ENTITY" OF THE SYMPATHETIC SYSTEM

In chorea, the raised basic blood pressure is responsible for a disturbance of the nourishment of one or more parts of the body. A "choreic reflex" is interesting as suggestive of some interference with the blood supply to the afferent parts of the nervous system, especially in the neighbourhood of the mid-brain, and the fact that I have seen this dorsal reflex in a case of encephalitis tends to support my doctrine. The interest of the reflex lies in its extent, since this corresponds with that part of the sympathetic system below the lower cervical ganglion. Here we have, so to speak, an entity of the sympathetic system in close co-operation with the solar plexus and the hypogastric plexus. The parts or organs supplied by this "entity" are those which are so readily affected in all temporary nerve storms (for example, hysteria), when the vascular reactions of the skin of the back and abdominal wall are so very active. It seems to me that this "entity" of the sympathetic acts as a centre for controlling the balance of all the basic blood pressures in various parts of the body, a presumption that is supported by the fact that in Addison's disease, with its low basic blood pressure, the semilunar ganglia are irritated or destroyed. If this suggestion has any value in it, it helps to emphasize the great desirability of having the basic blood pressure taken in all cases, because when it is raised it is certain that the balance of basic pressures is disturbed. At present, however, most medical officers who work for insurance companies hesitate to accept any of the estimations of the basic pressure, knowing that the majority of practitioners find a great difficulty in taking it. Personally, I am convinced that the auscultatory method is fundamentally wrong, both in theory and in practice. We need an objective method which will enable all medical men to make an estimate of the basic pressure quickly, correctly, and easily, because an increase in this pressure means that the body is upset by a poison which has been introduced into or developed in it.

TREATMENT

When we consider treatment there is an additional interest added to the whole problem. We must recognize that the disorders are due to a shortage of calcium in the first instance, and must understand that *until* that shortage of calcium is reduced we cannot hope to get much success. Treatment should therefore consist in giving salts of lime in a way which allows of its ready absorption, because although the calcium may be sufficient in quantity, its form may be very unsatisfactory. Much depends upon whether the lime is merely in solution as an inorganic salt, is combined with some organic base, or is in the colloid form. My experience in a large number of cases of chorea and of acute rheumatism is that calcium lactate given with parathyroid extract tends to lower the basic blood pressure; as the latter falls, the other signs and symptoms quickly diminish. In the more chronic varieties of raised blood pressure due to internally produced toxins the response to calcium and parathyroid is often equally satisfactory.

We know the value of lime in cases of disturbed exudation, and it must surely follow that when the basic blood pressure is raised the exudative processes are seriously affected. This is the condition in many of the urticarias and similar exudative disturbances, so that by working from either end of the argument we come to the conclusion that the exhibition of lime salts with parathyroid is useful in cases of raised basic blood pressure.

Finally we must remember that there is a unity linking up all diseases or disorders of the body, or, as I prefer to express it, "disease is in all cases merely an intensification of a normal process at a point where the pressure has been increased, just as electricity is the intensification of the normal motion of electrons giving rise to a pressure which bursts all restraint."

PYURIA AND BACILLURIA IN CHILDREN

BY

J. N. CUMINGS, M.B., M.R.C.P.

(From the Children's Department, King's College Hospital)

This paper consists of two parts, both of which deal primarily with normal children, but some remarks have been added concerning abnormal cases in which the methods developed for investigating the former have been employed.

Cuthbert Dukes[1] has described a method of counting pus cells in urine by which a definite comparison can be made between specimens from several children or between consecutive specimens from one child. He also defines "pyuria," limiting the term in adults to those cases which show more than 100 pus cells per c.mm. He regards figures between 10 and 100 per c.mm. in adults as indicating "excess of leucocytes" and figures below 10 per c.mm. as being within normal limits.[2] He describes a urine as containing so many pus cells per c.mm. instead of so many cells per field of a microscope. There can be no doubt that this method, although it involves a little more trouble, is more accurate. It could be adopted especially in hospitals, and would not be very difficult to carry out in general practice. The method employed in this investigation is a slight modification of that of Cuthbert Dukes, and will first be described.

Method of Counting Pus Cells in Urine

When a fresh specimen of urine has been collected and well mixed, a drop is placed with a pipette on an ordinary counting chamber, such as is used in making a red or white blood corpuscle count. The counting of the pus cells is done as in a white blood corpuscle count, the total number being enumerated in 1/2 or 1 c.cm. In a female child with a vaginal discharge thorough washing must first be carried out around the vulva and urethral orifice with a lotion such as boric acid or normal saline, only the second portion of the specimen being retained.

Results of Investigation

A series of eighty-eight boys was examined, all of whom could be considered as normal, their ages ranging from 7 weeks to 12 years. Of these, eighty-five had no pus cells per c.mm. The other three had 2, 4, and 2 pus cells per c.mm., their ages being 8, 6, and 12 years respectively. Only 3.4 per cent. of healthy boys, therefore, had even the slightest abnormality in the nature of pus cells in their urine.

A series of eighty girls was taken, all of whom appeared to be normal, with ages ranging from 8½ months to 11 years. Of these, thirty-six had no pus cells per c.mm.—that is, 55 per cent. of the girls had a certain number of pus cells present in their urine. The highest count was obtained in a girl, aged 10 years, who had 64 per c.mm.; the next highest was 44; then followed 28, 24, and 22. There were seven between 10 and 22, twelve between 5 and 10, and twenty between 0 and 5. None of these children had any urinary symptoms or vaginal discharge, nor would any of the cases fall within Cuthbert Dukes's definition of "pyuria," but twelve would be classed among the "excess of leucocytes" group, and therefore would be presumably abnormal.

The above figures give some data on which to consider abnormal cases, such as those of children suffering from pyelitis and cystitis.

Cystitis

The details of the following three cases of cystitis show the gradual reduction in the number of pus cells in the urine. Each table indicates the method of treatment and whether the urine was clear or opalescent.

Cystitis, Female, aged 10 years

Date	No. of Cells per c.mm.	Character of Urine	Treatment Adopted
1929			
Dec. 31	3,560	Opalescent	Pot. cit., gr. 200 per diem
1930			
Jan. 1	2,776	Opalescent	
Jan. 8	918	Opalescent	
Jan. 10	18,000	Opalescent	Jan. 9th. Hexamine, gr. 20 per diem
Jan. 11	268	Very slightly opalescent	
Jan. 20	160	Not opalescent, but not quite clear	
Feb. 1	10	Clear	
March 3	2	Clear	

Cystitis, Female, aged 8 years

Date	No. of Cells per c.mm.	Character of Urine	Treatment Adopted
1930			
Jan. 21	7,000	Opalescent	Pot. cit., gr. 80 per diem
Feb. 1	700	Opalescent	Jan. 24th. Hexamine gr. 20 per diem
Feb. 5	11,920	Opalescent	Feb. 5th. Pot. cit., gr. 120 per diem
Feb. 14	28	Clear	Feb. 10th. Pot. cit., gr. 160 per diem
Feb. 17	8	Clear	

Cystitis, Female, aged 2 years

Date	No. of Cells per c.mm.	Character of Urine	Treatment Adopted
1930			
April 16	6,200	Opalescent	April 17th. Hexamine gr. 8 per diem
April 27	600	Opalescent	
May 7	62	Clear	
May 20	8	Clear	

The object in giving the above tables in full is to demonstrate the value of an accurate count, and to indicate how much easier it is to follow the progress of the case by this method.

Pyelitis

Of three patients with pyelitis, one was a male infant aged 6 months, another a boy aged 10 months; the third was a girl aged 2 years. The first two cases have been very resistant to treatment, the number of pus cells having fluctuated from 300 up to 40,000 per c.mm. in both cases, with an average figure of about 2,000. The third case is recorded in the form of a table to show the effect of treatment, which was successful, as the figures indicate.

Pyelitis, Female, aged 2 years

Date	No. of Cells per c.mm.	Character of Urine	Treatment Adopted
1930			
Feb. 17	3,240	Opalescent	Feb. 17th. Pot. cit., gr. 96 per diem
Feb. 19	4,000	Opalescent	
Feb. 22	450	Less opalescent	
Feb. 26	14	Clear	
March 9	14	Clear	
March 13	36	Clear	
March 23	0	Clear	

Pus Cell Count in Other Conditions

A few additional cases of interest will now be mentioned. The first is that of a boy, aged 15 months, who had a septic sore on his foreskin, yet the number of pus cells per c.mm. was only 4. In a girl aged 10 years, suffering from haemorrhagic nephritis, there were 24 pus cells and 300 red blood corpuscles per c.mm. A boy, aged 7 years, with acute nephritis had 10 pus cells and 84 red blood corpuscles per c.mm. Another girl, aged 9½ years, who had just had scarlet fever, was found to have 282 (and on a second occasion 290) pus cells and 16 red blood corpuscles per c.mm. The last case in this series is that of a girl, aged 10 years, who had a vaginal discharge. The urine showed 192 pus cells per c.mm. on the first examination; twelve days later there were 500, but after efficient treatment for eight days the number was only 44—too low for Cuthbert Dukes's definition of "pyuria," but within his figures for "excess of leucocytes."

Numerical Definition of "Pyuria"

The question what figure should be considered to constitute "pyuria," and what figure separates normal from abnormal, is of considerable interest. From the above observations it is suggested that in boys figures of over 10 per c.mm., and in girls over 100 per c.mm., should be regarded as abnormal and of pathological significance—that is, "pyuria." The term "excess of leucocytes" would seem to be superfluous.

Necessity for Microscopical Examination

Another point is whether urine containing the low pathological figures can be recognized with the naked eye, and at what figure definite opalescence occurs. From the above investigations it was seen that figures over 200 per c.mm. represented just opalescent urine, while below that figure the urine was clear. It is a fallacy, therefore, to say that pyuria can be recognized by naked-eye examination of the urine; it requires a microscopical examination to settle this important point.

BACILLURIA IN NORMAL CHILDREN

A series of forty normal children was taken. Two specimens of urine were collected from each child, one in the ordinary manner, the other being obtained by collecting the urine in sterile test tubes after the penis or the vulva had been cleaned with boric acid lotion followed by sterile normal saline. The latter is referred to as the "clean" specimen. Cultures were put up on agar from both specimens, and incubated for twenty-four hours. The nature of the growth, if any, was then investigated, and the results classified in three groups.

Group 1 consisted of those children whose urine was sterile both in the clean and in the ordinary specimens. There were nineteen in this section—thirteen boys and six girls.

Group 2 consisted of fifteen children—five boys and ten girls. The clean specimens were sterile, but the ordinary specimens were contaminated. No organisms, therefore, were present in the urine of the children in this group. Organisms in the ordinary specimens must have been due to external contamination.

Group 3 consisted of four girls and two baby boys. In all *B. coli* were grown from both specimens.

In 90 per cent. of the twenty boys the clean specimens were sterile; if the infants are excluded—and it is very problematic whether it is possible to exclude contamination in these—100 per cent. had no organisms in their urine. The urine was sterile in 80 per cent. of the twenty girls.

Careful study of the three groups reveals that the proportion of girls to boys in each increases from Group 1 to Group 3, and that only in six girls were the ordinary specimens not contaminated. This seems to be strong evidence that in the remaining 20 per cent. organisms were present in the clean specimens owing to some external contamination, and that it is much more difficult to obtain a clean specimen from a female child than from a male child. The fact that there were no boys (excluding infants) from Group 3 also favours this view. One may conclude that the presence of organisms in the urine of a child is abnormal, though it does not necessarily indicate a pathological lesion of the urinary tract.

SUMMARY

1. The presence of leucocytes in the urine of normal children does occur; in boys as many as 10 per c.mm. can be considered as being within normal limits; in girls as many as 100 per c.mm. (the urine having been collected without any precautions). Figures exceeding these should be regarded as having pathological significance.

2. The enumeration of pus cells by the method described above might be more widely adopted, as it forms an accurate means of following the progress of a case from day to day and of comparing one case with another.

3. Bacilluria does not occur in normal children.

My thanks are due to Professor Still for permission to publish particulars about some of these cases, and to Dr. W. P. H. Sheldon for his untiring help throughout these investigations.

THERAPEUTIC EVALUATION IN THE TREATMENT OF SYPHILIS

BY

E. TYTLER BURKE, D.S.O., M.B., CH.B.

DIRECTOR OF MUNICIPAL CLINIC (V.D.), SALFORD

In estimating the amount of treatment which can be considered adequate for any case of syphilis, at least three elements must be taken into consideration: (1) the nature of the agents used; (2) the dosage given; and (3) the period over which they have been administered.

One syphilologist may find that in primary seronegative syphilis cure can only be brought about by the administration, during a period of thirty-six weeks, of 12.6 grams of an arsenobenzene compound (Ab. C.) plus that of a bismuth preparation in which the metal content amounts to 7.2 grams. Another may claim that by adopting a different principle of treatment, and by using either the same or different agents, cure can be attained in twenty-six weeks by giving 10.35 grams of Ab. C. together with a bismuth preparation in which the total quantity of the element amounts to 1.28 grams. It is not necessary to consider here which of the two methods is correct, or if one is more accurate than the other. What it is desired to point out is that the mode of assessing the amount of therapy administered is unsound, and does not present a true picture of the position.

DOSAGE

The first point to observe is that the Ab. C. dosage is expressed in terms of the actual compound itself (not of the arsenic), whereas that of the bismuth takes cognizance only of the elemental content. Now the therapeutic potency of an arsenical agent in the treatment of syphilis does not vary directly with its arsenic content. Various compounds contain various amounts of the element, from 18 to 22 per cent. or more. The pentavalent arsenicals such as stovarsol and tryparsamide are of lower therapeutic value than the trivalents, although their respective arsenic contents are 27 and 25 per cent. The dosage of Ab. C. is regulated not by the amount of arsenic present,

but by the toxicity of the compound itself, and this again is not in proportion to the quantity of element. The toxic dose of arsenic is 0.12 gram, but the amount of Ab. C. which would require to be given to get that quantity of arsenic into a patient would be more than 7 grams. Yet poisoning can take place from the administration of an amount of Ab. C. very far short of that. Neither the therapeutic potency nor the toxicity of the organic arsenical agents can be expressed in terms of the contained arsenic.

The bismuth preparations show a similar picture with respect to their bismuth contents. The percentage of elemental bismuth may vary from 4 to 60 or more. And here again animal experiment and clinical observation show that therapeutic potency does not depend upon the amount of bismuth present. A preparation with a bismuth content of 50 per cent. may be of considerably lower value as a treponemicide than one with a content of only 20 per cent. Levaditi has recently shown that bivatol, which consists of basic α-carboxethyl-β-methyl nonoate of bismuth dissolved in a fatty vehicle, is easily the most potent bismuth preparation in our armamentarium, though it contains only 4 per cent. of the element. My clinical experience fully bears this out, and shows that bivatol is practically equal in power to an arsenobenzene compound. It seems quite clear that a statement of the amount of bismuth therapy given to a patient is meaningless when expressed in terms of the metal; 5 grams of bismuth administered in one compound may not have so high a therapeutic value as half that amount when given in another combination. Therapeutic value depends upon the "usability" of the contained metal.

STANDARDIZATION

The Medical Advisory Board of the British Social Hygiene Council has urged that some action should be taken to standardize and control bismuth preparations used in the treatment of syphilis. This is necessary, but it does not seem to be yet realized that any attempt at standardization based upon the bismuth content must be futile. I suggest that the only satisfactory way in which standardization can be brought about is by taking into account the chemotherapeutic indices of the various agents. The chemotherapeutic index is expressed as the maximal tolerated dose per kilo divided by the minimal curative dose per kilo. For example, if the former is 0.120 gram and the latter 0.004 gram, the equation would read:

$$\frac{0.120}{0.004} = 30 \approx \text{chemotherapeutic index.}$$

In other words, the minimal curative dose is one-thirtieth of the maximum tolerated dose.

There exists a very clear and direct ratio between the chemotherapeutic index (C.T.I.) of an Ab. C. or a bismuth preparation and its therapeutic value. The various groups of remedial agents may be arranged roughly according to their C.T.I.'s in the following descending order:

Agent	C.T.I.	Efficiency Scale	Therapeutic Value in Units
Ab. C. (Stabilarsan, N.A.B.)	15	100	1
Bivatol	12	75	0.75
Bismuth metal suspension	8	50	0.5
Tryparsamide, etc.	5	31	0.31
Mercury	1	6	0.06

The place of the agent upon the efficiency scale is proportional to the C.T.I., and so likewise is its therapeutic value. Ab. C. being the most potent, its therapeutic value (T.V.) is taken as unity. The others are expressed as decimal parts of it.

Now in the therapy of syphilis regard must be had not only to the amount of drug given, but also to the time within which a certain dosage is administered. There is a *two-dimensional* "*time-quantity*" *factor*, which is of essential importance. It is best, in my view, to look upon the time element as consisting of one week. In that seven-day period one records that a certain number, or fractional parts, of therapeutic units (*T.U.'s*) have been given. It has to be assumed that whatever the amount administered it has been the optimum amount for that seven-day period. Thus if 0.45 gram of stabilarsan is given in one week a dose of 1 T.U. is recorded. Although 0.6 gram may be given the next week, that is also reckoned as 1 T.U. Similarly, in a child or delicate person, 0.15 gram is also 1 T.U. In the Salford Municipal Clinic the agents used are stabilarsan, bivatol, and tryparsamide or stovarsol. As will be seen from the above table, however much or little of stabilarsan, bivatol, or stovarsol is given during a period of seven days, it is reckoned as 1, 0.75, or 0.31 therapeutic unit respectively. The Salford routine course of treatment for a case of sero-negative primary syphilis is, according to the general method of reckoning, stated as follows:

Stabilarsan once weekly for 6 weeks (total 3.45 grams).
Bivatol twice weekly for 4 weeks (total Bi 0.64 gram).
Stabilarsan once weekly for 6 weeks (total 3.45 grams).
Bivatol twice weekly for 4 weeks (total Bi 0.64 gram).
Stabilarsan once weekly for 6 weeks (total 3.45 grams).
Giving a total of 10.35 grams of stabilarsan and 1.28 grams of bismuth metal in 26 weeks.

The above, of course, conveys no idea whatever of the real therapeutic picture, because there is no relationship or comparability between grams of Ab. C. and grams of metallic bismuth so far as curative value is concerned. If, however, we state the treatment in terms of therapeutic units calculated as indicated above, we do get a useful comparison, thus:

Stabilarsan once weekly for 6 weeks (total 6 therapeutic units).
Bivatol twice weekly for 4 weeks (total 3 therapeutic units).
Stabilarsan once weekly for 6 weeks (total 6 therapeutic units).
Bivatol twice weekly for 4 weeks (total 3 therapeutic units).
Stabilarsan once weekly for 6 weeks (total 6 therapeutic units).
Giving a total of 24 therapeutic units (stabilarsan 18, bivatol 6) in 26 weeks.

The number of therapeutic units given in a series of injections is the product of the number of weeks and the unit therapeutic value of the drug in question; thus, a four-week bivatol series is calculated as $4 \times 0.75 = 3$ T.U.

The Salford experience, then, is that the minimum amount of treatment necessary to secure a satisfactory percentage of cures in sero-negative primary syphilis is 24 therapeutic units given in twenty-six weeks.

APPLICATION TO OTHER COURSES

This system of evaluation may be applied to other courses of treatment. In several other treatment centres the minimum prescription for a sero-negative primary case is 12.6 grams of Ab. C. with 7.2 grams of bismuth metal in thirty-six weeks. The Ab. C. is given in two series of ten injections at weekly intervals, with a rest period between series. In this way 20 therapeutic units of Ab. C. are injected. Supposing that a bismuth metal suspension is used, the C.T.I. will be in the region of 8. This preparation would be allotted, therefore, the value of 50 on the efficiency scale, which means a therapeutic value of 0.5 T.U. Nine injections of this bismuth agent are given at weekly intervals concurrently with the Ab. C.—that is, eighteen weeks in

all of bismuth therapy. The total number of therapeutic units of bismuth given will then equal 18 × 0.5—that is, 9 T.U. In this case we have the experience that a total of 29 T.U. must be given to obtain a satisfactory percentage of cures. On account of concurrent administration it is necessary to interrupt the treatment by rest intervals, so that thirty-six weeks are occupied in completing treatment, as against twenty-six at Salford.

The net therapeutic efficiency (N.T.E.) of treatment must take into account the time occupied in attaining cure, and this may be expressed by the equation:

$$\text{N.T.E.} = \frac{\text{Total therapeutic units} \times 100}{\text{Weeks occupied by treatment}}$$

Therefore

$$\text{Salford N.T.E.} = \frac{24 \times 100}{26} = 92$$

Whereas

$$\text{the other N.T.E.} = \frac{29 \times 100}{36} = 81$$

According to this scheme of reckoning there would appear to be a balance of 11 points of net therapeutic efficiency in favour of the Salford method, or, in other words, a saving of time of ten weeks, and of an appreciable quantity of remedial agent (5 T.U.).

It is not, however, my purpose here to open a controversy as to alternating *versus* concurrent treatment. I wish merely to suggest that a standardization of therapeutic values be made along the lines I have indicated; this might well be adopted by the Ministry of Health. Upon some standard animal experimentally infected, it is necessary to work out the chemotherapeutic indices of the various chemical agents. From these one could, in a way which is at present impossible, compare the relative values of different modes of treatment and go far towards settling the vexed question of what constitutes adequacy. Not until some such standardization is adopted will it be possible to check the tremendous amount of inefficient therapy that is now being prescribed in all good faith. I submit the foregoing suggestions as a "preliminary note" in the hope that they may stimulate someone with more competence and greater leisure than I have, to explore the paths indicated. I have here only attempted to enunciate general principles; the various details—mathematical, biochemical, and so on—can only be elucidated and proved by experiment.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

FRACTURED NECK OF THE FEMUR TREATED BY INJECTION OF BLOOD

In an article on union and non-union of fractures[1] Blundell Bankart described a case of typical intracapsular fracture of the neck of the femur successfully treated by injection of blood into the site of the fracture, combined with reduction by skeletal traction. The object of the present note is to place on record another such case treated in the same way with a similar successful result.

A man, aged 34, fell from his bicycle in December, 1929, and was unable to use his left leg. After admission and *x*-ray examination elsewhere he was transferred to the Hospital of St. John and St. Elizabeth with all the signs of an intracapsular fracture of the neck of the left femur. There was considerable external rotation, but little shortening. Twenty-four hours after the accident blood was withdrawn from the median basilic vein and 10 c.cm. injected into the left hip-joint. The limb was then abducted and slung in a Hodgen splint, and an extension of 15 lb. applied to the femur by means of ice-tong callipers inserted under local anaesthesia. Subsequent *x*-ray examination showed a good position, and this extension was maintained for three weeks, when strapping extension of 8½ lb. was substituted. During the whole time the knee was kept movable by means of a knee flexion piece, and massage was given to the hip. A further radiogram six weeks after reduction showed a little new bone formation; all extension was then removed, and massage given to the whole leg for a further fortnight, during which time the patient was fitted with a walking calliper splint. After discharge he was able to return to his work at a lathe wearing the splint; it was finally omitted three months later, when a radiogram showed bony union in good position. All movements at the hip-joint were full and painless; flexion at the knee was possible to more than a right angle, and has increased since the calliper was left off.

[1] Bankart, A. S. B.: *British Medical Journal*, 1930, i, 8.

Commentary

Even in young people these fractures show a tendency to non-union, and by ordinary methods of treatment must be immobilized for a long period. In this case there was both *x*-ray and clinical evidence of union after six weeks.

It is important that the blood should be injected into the joint itself; the average capacity of the adult hip-joint as estimated from a number of cases injected post mortem is 14 c.cm. When the point of the injecting needle is in the right place there is considerable resistance to the injection; in the case described by Bankart I was able to feel the fractured surface.

With a suitably adjusted extension and counterpoise of the leg the patient can remain sitting up in bed throughout the treatment.

The addition of a knee flexion piece from the outset is of considerable help in preventing stiffness of the knee later on.

E. W. RICHES, *M.C.*, M.S., F.R.C.S.
Assistant Surgeon to the Middlesex Hospital and to the Hospital of St. John and St. Elizabeth.

HODGKIN'S DISEASE WITH UNUSUAL ONSET

The following case appears worthy of mention on account of the rather unusual first symptom and of the rapid termination.

T. W. R., aged 47, a well-nourished and previously quite healthy man, noticed in February, 1930, that he was becoming hoarse. As the huskiness did not yield to simple remedies he had several carious teeth extracted. This procedure was followed by some slight enlargement of the glands in the neck. In June he was admitted to the Derby City Hospital as the hoarseness still persisted and the glands in the neck were increasing in size.

On examination, he was well developed and well nourished, but was rather anaemic in appearance. On both sides of the neck were present moderately large masses of discrete glands which had the general characteristics of lymphadenoma. His one complaint was that of hoarseness. Laryngeal examination revealed a nodule situated on the left cord and some general oedematous thickening of both cords, which were movable. No other glands were palpable apart from those in the neck, nor could the spleen be palpated. The Wassermann reaction was negative, and the blood picture showed a secondary anaemia with no marked increase in eosinophils.

A gland was removed from the neck under local anaesthesia, and the pathological report stated: "The gland is destroyed by a cellular tissue with relatively little stroma and large areas of necrosis. The appearances are suggestive of acute Hodgkin's disease." A screen examination of the chest showed a mass irregular in shape in the mediastinum. Some fourteen days after admission discrete glands appeared in both axillae. The glands rapidly increased in size, and ultimately caused extreme oedema of both arms. The patient's condition rapidly grew worse, and he died after just over one month in hospital and barely six months from the appearance of the first symptom. Whilst in hospital, the patient had a temperature of the Pel-Ebstein type.

At the necropsy masses of discrete glands were found on both sides of the neck and in both axillae, but none were present in the groins. A mass of glands of moderate size was situated in the mediastinum and there was some terminal broncho-pneumonia. No enlarged glands were found in the abdominal cavity, and apart from the larynx all the other organs were moderately healthy in appearance. Upon opening the larynx a nodule about the size of a small bean was seen to be present on the left cord, and the surface of the nodule was ulcerated. The pathological report on the cords stated: "The deeper tissues are infiltrated by what appears to be lymphadenoma, and over this ulceration has occurred."

In this case it seems reasonable to assume that the hoarseness was due in the first place to the lymphadenomatous infiltration of the cords in spite of any effect which may have been produced by the pressure of glands. If so, it is rather unusual that this should have been the first symptom complained of, and that it was present before any enlarged glands were noticed by him.

I am indebted to Professor Haswell Wilson for the pathological reports.

R. G. COOKE, M.D.,
Medical Superintendent,
City Hospital, Derby.

FISHBONES IN THE APPENDIX

The following case may be of interest in view of the ever-varying symptoms in connexion with disease of the appendix.

A labourer, aged 40, was admitted to hospital complaining of acute pain on micturition, with vague abdominal pain. He gave a history of having had severe pain on micturition for about two years, also of vague abdominal pains which came on at indefinite intervals of from six weeks to three months and lasted from one to three days; this condition had persisted two years, and the history was confirmed by the district medical officer.

The patient was a well-nourished man, and did not look ill. There was nothing abnormal in the appearance of the abdomen, and palpation revealed no trace of rigidity or tenderness, with the exception of a small area one inch square immediately above the symphysis pubis; this was not constant from day to day. There were no areas of hyperaesthesia to pin-stroke, and both the obturator test and rectal examination proved negative. The patient gave a history of constipation. Examination of the urethra with bougies and the urethroscope showed nothing abnormal; the bladder, urine, and faeces appeared normal, and there was no leucocytosis.

After five days in hospital a severe attack of abdominal pain developed, and the patient lay on his right side with both knees drawn up; he had no temperature, but the pulse had slightly increased. There was no nausea or vomiting then or at any other time, his only complaint being epigastric pain. The usual mild treatment was given for colic, and the attack passed off in about two hours. It was followed, however, one hour and a half later, by a similar attack, which lasted three-quarters of an hour, and again by a third attack two hours later, which persisted for one and a half hours. During each attack there was no rigidity of the abdominal wall, and no tenderness could be elicited anywhere. There was frequent desire to micturate; the bladder emptied each time to the extent of one to three ounces, severe pain being caused thereby.

In spite of the absence of *x*-ray and cystoscopic examinations, I decided to open the abdomen. Through a lower midline incision I examined the abdominal contents, but could detect nothing abnormal. The appendix was then exposed and found to be about 5 inches long; it was slightly thickened at the distal end, and was dilated in three places by concretions. Definite signs of a foreign body were also obtained, and on cutting the appendix open I found eight fishbones, which ranged in length from 0.3 to 2.3 cm. The patient made an uneventful recovery, and there was no return of the colic. The pain on micturition slowly decreased, disappearing finally about the sixth day after operation. He left the hospital on the fourteenth day and has had no further attacks during the two months which have since elapsed.

Permission to report this case has been kindly given by Major Sutherland Richards, *M.C.*, M.D., chief medical and health officer.

MATTHEW CLAYTON-MITCHELL,
Resident Surgeon, Colony Hospital, Grenada,
British West Indies.

Reports of Societies

HIGH CARBOHYDRATE DIET IN DIABETES

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on February 10th, with Dr. PHILIP HAMILL in the chair, the discussion was devoted to the use of high carbohydrate diet in the treatment of diabetes.

Dr. E. P. POULTON said that the dieting of diabetics had been influenced by three considerations: the scarcity of insulin, the extreme value of fasting, and the belief that it was easier to get a correct balance between insulin and carbohydrate so as to maintain a low blood sugar. Although patients had done well in general under this treatment, it could not be said that there had been any striking amelioration of the disease in many cases, and in children it had, in his experience, been disappointing. In the autumn of 1928 he decided to try a higher carbohydrate diet, and although the attempts were tentatively made at first, there had since been a landslide away from the older strict dieting in favour of a more liberal carbohydrate allowance. Dr. Poulton brought forward twenty-seven cases showing that with this increase the insulin requirement remained very constant. He took the view that those persons who were on insulin could be given higher carbohydrate diets with advantage. Patients felt very much better with them, and some of them had conditions, such as phthisis, in which large amounts of carbohydrate were required. He also showed some modified diet tables which he had worked out.

Dr. R. D. LAWRENCE said that he had used high carbohydrate diets experimentally in certain cases in 1926 and 1927, but he then found extreme difficulty in preventing hypoglycaemia. In these cases about 70 units of insulin and 200 grams of carbohydrate were taken per day. He had now joined everybody else in giving higher carbohydrate diets than formerly, but the allowance he gave was from 70 to 120 grams, and with such a diet most of the patients got all the toast, bread, and fresh fruit they wanted; it was not a normal diet, but it satisfied them, and had no disadvantages.

Dr. T. C. HUNT said that during the time he was working in Vienna he found 165 grams of carbohydrate being given in Professor Falta's clinic, with approximately 100 grams of protein, and was impressed by the results. The object of restricted carbohydrate diet must be to assist pancreatic regeneration. The evidence that high blood sugars actually caused further degeneration of the pancreatic tissues, or that very low blood sugars caused regeneration, was somewhat indefinite. The differences between the results with a very restricted carbohydrate intake and a fairly free one were not so great as might be expected. The higher carbohydrate diet certainly made easier the choice of foods.

Professor J. A. NIXON said that he had been using a higher carbohydrate value in diet since 1922, when he was first able to obtain insulin. From the outset he took the line that the purpose of insulin was to enable patients to use carbohydrate if possible in normal quantities. He had never gone so high as some American observers, but

he had fairly consistently allowed 100 to 150 grams of carbohydrate per day, and, of course, in order to do that it was necessary to give large doses of insulin. His experience, he thought, did not differ greatly from that of other workers. He could not claim that more patients had been able to do without insulin. Every now and then he came across a patient in whom there was some regeneration of the power of using up carbohydrate, but he could not claim any more than just the average improvement. The number of patients who had been able to do without insulin was relatively small. But the thing that did impress him was that the patients stuck to their rules very much better, and had their diet as prescribed. The majority of people in this country were not very big meat-eaters, and they did not want to be "pushed up" in the matter of proteins. With the more adequate amounts of carbohydrate the principal gain was the patient's added contentment. He could not say yet whether these adequate carbohydrate diets were having any marked influence on the condition of the arteries.

Dr. A. P. THOMSON said that anyone who had control of a large out-patient clinic for diabetes must have had certain facts brought to his attention. During the first two years of insulin treatment in his out-patient department he was in the habit of assembling those patients who had obviously broken their dietary rules, and prophesying evil to them. At the end of two years he reviewed the whole of his cases, and in honesty he had to confess that the patients who had disobeyed him had done rather better than those who had obeyed him, and certainly they were a healthier and more cheerful crowd. That was purely a clinical observation; it was not supported by the laboratory findings. He came to the conclusion that it would be wise to try a mass experiment. He reviewed 400 cases of which there were fairly good records for five years, and whose diet had been round about 100 grams of carbohydrates. If the patient was taking roughly that amount, the amount of protein and fat he took had far better be determined by his own appetite. He was convinced that it was now a practical thing to say to the patients that they might take 100 or 120 grams of carbohydrate a day, balance them on insulin, and tell them to determine their own protein and fat. The extraordinary thing was that the blood sugar remained fairly constant. He deprecated too much reliance on laboratory figures; the question was a clinical one. The diabetic was human, and his diet varied according to energy requirements and the kind of life he lived. The extraordinary vicissitudes in the home life of out-patients made a rigid dietary out of the question. Dr. Thomson added that in a straightforward case he had never seen any improvement in tolerance after six months from the onset of the condition. A system of dealing with these patients had been formed which amounted to this, that in an acute patient treated shortly after the onset of the disease a strict regime was enforced; at the end of six months the patient was again assessed, and then placed on an unrestricted diet with adequate carbohydrates. On the adequate carbohydrate diet the physical development of children was very much improved; on the restricted diet they tended to have a bad figure.

Dr. O. LEYTON thought that any standard diet was a medical impertinence. In his diet book the average had been 120 grams of carbohydrate, and he thought the average man was satisfied with that. In the hospital it was only exceptionally possible to arrange matters so that a patient could keep a blood sugar below 1.5 per cent., and among his own hospital patients it was very rare for one to be able to stop taking insulin. He added that in some cases alcohol seemed to act as a deterrent to the regeneration of the pancreas.

Dr. GEORGE GRAHAM said that during the last year he had been increasing the figure for carbohydrate from 50 grams, at which he used to work, to about 100 grams, and he found that these patients were improved. With regard to fat in the diet, he had not worked lower than 100 grams of fat, and it was an open question as to what was the right amount. It was necessary to aim at a balance between the amount of fat and carbohydrate in the diet, and this was going to be difficult, because it would take a long time to discover whether they were doing better on a diet or not. One point was that some of the patients were extraordinarily difficult to keep free from acetone bodies, and this raised the question whether those who had a diet of high carbohydrate value were in greater danger of coma than those on a restricted carbohydrate diet.

Dr. P. J. CAMMIDGE said that insulin might be regarded from two points of view: as a curative agent, or as substitution therapy. For his own part he never expected that insulin was going to cure diabetes. It should be used simply as a means of obtaining as far as possible a normal diet, and the so-called "high" carbohydrate diets were an attempt to get back to the ordinary average condition. The average person's diet consisted of 100 grams of protein, 80 to 100 grams of fat, and 300 to 500 grams of carbohydrate. His personal experience was that a good deal depended upon the ratio between carbohydrate and fat, not only when using insulin, but also in cases where the use of insulin was not necessary. These higher carbohydrate diets were very useful in children, who did well, except in a few cases which had in addition pituitary disturbances, in which event carbohydrate did not act as it did in other children. The nearer the diet of the diabetic could approach to the ordinary average diet, the more satisfactory it was to the patient.

Dr. PAUL WEISS (Bad Homburg) gave some account of Continental work, and distinguished between different sources of carbohydrate, expressing an opinion in favour of additional vegetable and fruit diet, and less bread. The calcium in the vegetable diet was specially valuable for children, though calcium was needed by all diabetics. He added that insulin injections, especially with high carbohydrate diets, should be given strictly to time, preferably every eight hours.

Dr. POULTON, in a brief reply, commented on the unanimity of the opinion that carbohydrate diet should be raised, though there was not the same unanimity as to the extent of the increase.

MENTAL SYMPTOMS ASSOCIATED WITH BRAIN TUMOURS

At a joint meeting of the Sections of Neurology and Psychiatry of the Royal Society of Medicine, on February 12th, with Dr. KINNIER WILSON in the chair, a discussion on mental symptoms associated with brain tumours was opened by Dr. GORDON HOLMES.

It was rare, Dr. Holmes said, for the psychiatrist to find intracranial tumours in patients in mental hospitals, but the neurologist was aware that mental symptoms—frequently transient, sometimes severe—were associated with increased intracranial pressure. Schuster had recorded that among 528 cases of intracranial tumour 323, or 55 per cent., had shown mental changes. The cause of these was uncertain; some observers thought they were due to a diffuse inflammatory reaction in the meninges, but such a reaction was not constantly found, and when present was usually mild. Others believed the mental symptoms depended on cerebral intoxication due to degeneration of the tumour, but the evidence was not sufficient to support this view except in the case of infundibular ("stalk") tumours, which might give rise

to pyrexia and urticaria, or in the case of hydatid cysts. Oedema round the tumour was a common cause of mental disturbance; that apathy and drowsiness might result from impeded drainage of the cerebro-spinal fluid was shown by the relief of these symptoms by decompression or the intravenous injection of hypotonic solutions in certain cases. A few mental symptoms could be referred to given regions of the brain; drowsiness, for example, was associated with lesions of the tubero-infundibular region, certain character changes with the pituitary, and speech disturbances with lesions of the left hemisphere in right-handed persons. Injury to the motor centres giving rise to headache, vomiting, and epileptiform attacks, usually engendered a not unnatural depression in the patient which could hardly be classed as a mental change. Frontal tumours gave rise to mental changes more constantly than tumours in any other site, except the corpus callosum. The frontal lobes were not the seat of the intellect, but their function, as determined by extirpation experiments in animals, was probably the elaboration of mental data. Certain groups of mental symptoms could be distinguished in cases of cerebral tumour. In the first group were found apathy, indifference, passivity, delayed reactions, wandering attention, and amnesia. In the second group the patients showed depression and stupor; they were often incontinent, but were emotionally undisturbed by their condition; they tended to be confused, especially on waking; memory was unreliable. The third group occurred in patients who were restless, showing an irresponsible childishness, a lack of reserve, and a tendency to facetiousness alternating with depression. The fourth group of symptoms resembled those of general paralysis of the insane; the patient evinced a lack of higher control, failing memory, confusion, and paucity of expression. Dr. Holmes quoted case-histories illustrating the mental symptom-complexes which he had described. Although it was not yet possible with accuracy to localize a tumour by means of the mental symptoms he believed that a more intensive study would throw light on the action of the brain as the organ of the mind.

Dr. F. GOLLA said that the evidence in support of a neurological basis for the psychoses was discouraging. In his experience of psychotic patients, cerebral tumour, occurring as a terminal condition—too late to be regarded as a cause of the insanity—was found in 0.23 per cent. of cases; the incidence of cerebral tumour was the same in the sane population. In cases observed at Claybury, the Maudsley, and certain allied hospitals, where cerebral tumour was causally connected with insanity, there was an overwhelming predominance of temporal tumours, nineteen having occurred in this site out of a total of fifty-five. Six were on the left side and associated with aphasia; the remaining patients with temporal tumours were dull, confused, and amnesic. Facetiousness was a symptom in one patient with a parietal tumour, and in another with a frontal tumour; he believed this symptom to be a defensive reaction on the part of a patient who realized he was abnormal. He considered that it was difficult to explain mental symptoms on the ground of increased pressure alone; in his opinion the response of the enfeebled brain was determined by the previous trend of the mind and not by the anatomical site of the lesion.

Dr. RUSSELL BRAIN thought that it was difficult to separate local symptoms from the symptoms of increased intracranial pressure. He quoted several cases, in the first of which the mental changes had been due to hydrocephalus following occlusion by the tumour of the aqueduct of Sylvius, and in which there had been vertigo, diplopia, and stammering. In another patient, a woman with cerebellar tumour, there was a progressive neglect of cleanliness, a tendency to weep, irritability, and visual hallucinations. A third case underwent operation for angioma of the cerebellum, a local anaesthetic being used. As soon as the dura was opened a dramatic change came over the patient, who had previously been completely disorientated; he realized at once that he was in hospital and asked how the operation was progressing, showing that in this case the symptoms subsided with the reduction of intracranial pressure. Dr. Brain considered that mental disturbances were more apt to occur in the middle-aged than in the young, and that they might be associated with vascular changes. The same parts of the brain appeared to be disordered whether the pressure was immediate or remote.

Dr. J. BRANDER had found intracranial tumours to occur in less than 1/2 per cent. of total admissions in a mental hospital. Out of forty-four cases associated with mental symptoms twenty-eight had occurred in men; in cases of long-standing psychosis the development of tumour did not affect the mental state. Where a tumour was responsible for mental symptoms it might often be said that it had only rendered manifest a latent morbid tendency. He quoted several case-histories, in one of which the development of a tumour had precipitated the appearance of Korsakoff's syndrome, and two others in which fugue-like states had arisen, although the tumours were multiple secondary deposits in one case and a single frontal growth in the other. Five cases with naevoid tumours had shown epileptiform attacks, which had been diagnosed as idiopathic. In short, he believed that every variety of mental disturbance might be found, regardless of the site of the tumour.

Dr. N. G. HARRIS mentioned five cases of cerebral tumour found in 365 autopsies which he had performed since June, 1923. Contrary to the finding of Dr. Brander, four of these had occurred in women and only one in a man.

Dr. E. MAPOTHER was sceptical of the localizing value of any mental symptoms in cases of cerebral tumour; he thought there was more likely to be an accentuation of the normal temperament in the majority of patients. Dr. C. P. SYMONDS said he found it more and more difficult to determine any group of symptoms having a localizing value. He thought mental symptoms depended more on the amount of white matter destroyed than on the site. Dr. WORSTER-DROUGHT also doubted whether the tumour had much to do with the type of mental disturbance to which it gave rise. Much depended on the emotional make-up of the patient. Dr. I. FROST said he had been investigating the haemoglobin content of the blood in epileptics and had found a daily fluctuation which could not be explained on the grounds of anaemia. Was it possible, he asked, that naevi such as those described by Dr. Brander might act as reservoirs for the blood in those epileptic patients in which they were present?

The CHAIRMAN said that all neurologists appeared to agree that the localizing value of mental symptoms in cerebral tumour was relatively *nil*. In his opinion the importance lay, not in the position of the tumour, at one end of the brain or the other, but in the degree to which association between the two hemispheres was affected. It should be asked whether the tumour was related either to the corpus callosum or to the inferior longitudinal fasciculus, the two large association systems of the brain. Temporal tumours tended to involve the inferior longitudinal fasciculus, and frontal tumours the corpus callosum. Few patients with cerebral tumours ended their days in asylums, because the tumour was seldom large enough to give rise to a sufficient degree of mental disturbance.

INJECTION TREATMENT OF VARICOSE VEINS

In opening a discussion in the Aberdeen Medico-Chirurgical Society, on February 5th, on the causes of failure in the injection treatment of varicose veins, Mr. G. H. COLT began by briefly reviewing the history of the subject subsequent to Briquet's thesis of 1824; Brodie's description of Trendelenburg's sign over fifty years before it was given a name was mentioned, and the present tendency to confuse the issues by speaking of a negative Trendelenburg when a different and positive phenomenon was meant was deprecated. The introduction and growth of the injection treatment was briefly referred to, and the difficulty was mentioned of finding pathologically similar veins so that the various solutions and methods could be compared. Mere size, or varied degrees of tortuosity or rapid blood stream or intense superior abdominal reflux were all instanced as being unconnected with failure. Kosinski's painstaking anatomical work and Warwick's injection experiments on the cadaver were described and illustrated by the epidiascope. The radiological demonstration of varicosis was considered briefly and illustrated. The commonly accepted causes of varicosity were shown to be probably the chief factors making for recurrence, and if longer intervals (a month or more) were allowed to elapse between area flooding by the controlled method and the patient kept under observation for a year with very occasional further injections if necessary, recurrence, as such, appeared to be very rare. In the first series of 154 cases, of 137 limbs examined one year after cessation of treatment, further varicosity had appeared in 11, and these had been predicted in every case but six, where the skin was oedematous. The second series of limbs was very similar. A total of 1,674 injections had been carefully noted for 629 limbs (2.6 per limb), but until a satisfactory method of classification was universally used it would be impossible to compare results. Three cases in which the results were untoward were fully described. In one (not in either series) a pulmonary embolus had ended life thirty hours after abdominal section and seventeen days after the last injection. It was noteworthy that the patient had just recovered from influenza. In the second a right-sided hemiplegia had occurred in a healthy subject four days after the second injection, and good recovery had taken place. In the third, retrobulbar neuritis began a week after the last injection, and had given rise to a permanent slight dimness of vision in the affected eye. Apart from local necrosis, now becoming rare, the last two complications were the only ones in the total of 383 patients (629 limbs) treated.

At a meeting of the Osler Club on February 13th, Dr. A. P. CAWADIAS gave an address in memory of Dr. J. B. Hurry, entitled "The dynamic and the modern procedure of diagnosis." He said that the basis of the modern dynamic conception of disease was the integration of the human body by the psycho-neuro-endocrinic system. It was through this system that man adapted himself to his environment. Health was the product of perfect adaptation; disease or functional dissociation was the product of imperfect adaptation. Every diseased individual represented a chain of morbid events, with the following four links: external etiological factors, constitutional factors, psycho-neuro-endocrinic syndromes, and organ syndromes. The neo-Hippocratic diagnosis of the person determined the four links of the chain, and viewed the individual as a whole striving towards cure. Sir WILLIAM COLLINS proposed, and Mr. WARREN DAWSON seconded, a vote of thanks to the lecturer. Dr. Hurry's writings were on view, and the visitors included Dr. Hurry's son and daughter, Sir Humphry Rolleston, and Mr. Hastings Gilford.

Reviews

VITAMIN D

The chapter headings of *Ultraviolet Light and Vitamin D in Nutrition*,[1] by KATHARINE BLUNT and RUTH COWAN, promise a great deal; no less, in fact, than that every subject coming legitimately within the scope of this general title will receive attention. This promise is amply fulfilled. Beginning with a discussion of the experimental and statistical evidence for the view that growth may be controlled by biochemical methods, the authors review in succession, and with due regard to historical perspective, the facts and hypotheses relating to the dietary control of bone and tooth development, the antirachitic power of light, the interrelation of vitamin D and light, the physical and biochemical properties of the relevant parts of the spectrum, the metabolism of calcium and phosphorus in the body, the distribution of vitamin D, the activation of foods and ergosterol, the problem of the vitamin D requirements of adults, especially of women during pregnancy and lactation, and the prophylaxis and treatment of rickets. To try to cover so great a variety of topics in a work of little over two hundred pages may seem to be a rash undertaking; but so skilfully have the authors marshalled their facts that their presentation of the subject, terse though it may be, at no point fails to be adequate. The exhaustive references to the literature, a list of which appears at the end of each chapter, would alone serve to make this book invaluable to all workers on the problems with which it is concerned.

It is probable that in planning their work the authors had in mind the needs of the general physician and the dentist rather than of the biochemist actually engaged in investigating the relation of ultra-violet light and vitamin D to nutrition. But so enormous in sheer bulk has become the literature on this subject that even the specialist, who cannot but grudge the time he must spend in searching through innumerable periodicals and transactions of learned societies on the chance of finding a new fact, will be grateful for the authors' faithful and up-to-date summary of all that is valuable in this literature. They help him not only by their clear statements of established facts, but by their suggestive remarks on problems still to be investigated.

The work is well illustrated and sufficiently furnished with graphs and tables. It deserves a very good reception from the medical profession.

SURGICAL APPLIED ANATOMY

Handbooks on surgical applied anatomy have their uses and are appreciated by students, and the *Stepping Stones to Surgery*[2] of Mr. L. BATHE RAWLING will no doubt be much worn by the footsteps of students in time to come. "Holden's Landmarks" was a well-known and much-valued guide to past generations of students and practitioners. With his previous work, *Landmarks and Surface Markings of the Human Body*, Mr. Rawling has carried on the traditions of Holden in the same medical school. He tells us in his preface that this book, based upon lectures delivered at St. Bartholomew's Hospital on clinical applied anatomy, is intended to bridge the gap between anatomy and surgery. It does not profess to

[1] *Ultraviolet Light and Vitamin D in Nutrition*. By Katharine Blunt and Ruth Cowan. The University of Chicago Home Economics Series. Chicago, Illinois: University of Chicago Press; London: Cambridge University Press. 1930. (Pp. xiii + 229; 39 figures. 11s. 6d net.)

[2] *Stepping Stones to Surgery*. By L. Bathe Rawling, M.B., B.Ch., F.R.C.S. London: H. K. Lewis and Co., Ltd. 1930. (Pp. xvi + 228; 97 figures. 12s. 6d. net.)

include all the regions and parts of the human body, but the author hopes to extend its scope in later editions. Stepping stones to surgery must include a good deal of physiology as well as anatomy if they are to be really useful. Accordingly we find a number of physiological considerations discussed here, and we could wish that in his otherwise excellent disquisitions on joints Mr. Rawling had laid more stress on the importance of the muscles in producing and maintaining the stability of various joints, notably of the knee, beyond the statement, that "it derives its strength from the muscles and tendons related to it."

The plan of this book is essentially clinical, an individual case being taken as the text of each chapter and profitable lessons drawn from a discussion of the local anatomy and of the operative measures which may, or may not, be advisable for the relief of the conditions. The advice given is based on large experience, and is likely to prove of the greatest practical value. Perhaps intentionally Mr. Rawling has omitted all affections peculiar to the female sex, except cancer of the breast, the chapter on which is particularly instructive. The illustrations are all the more valuable for being in general somewhat diagrammatic. We note a printer's error in Figure 90, in which the lettering points to two external carotid arteries—one of which obviously should be labelled "Internal Carotid."

SKIN GRAFTING

Technique and Results of Grafting Skin,[3] by Mr. H. KENRICK CHRISTIE, is not, as its title might be thought to imply, a treatise on skin-grafting methods in general, but a handy volume of sixty-seven partly filled pages giving the author's experience in the treatment of a small series of cases. Its aim is to encourage the use by the general surgeon of the simpler forms of skin grafting, and more particularly of the Wolfe graft, in the treatment of chronic ulcers of the lower extremity. Two cases of recent trauma and one of webbed fingers, treated by Thiersch grafting, and one case of haemangioma of the face, treated by a combination of Thiersch and Wolfe grafting, are recorded to indicate the usefulness of similar grafts in other situations. Short chapters are devoted to biological and histological considerations, and the novel suggestion is made that the time may come when it may be possible to keep stock cultures of epithelium for immediate use where skin has been lost.

Instructions are given for the cutting and application of Wolfe and Thiersch grafts and the preparation and transfer of tubed pedicle flaps. No mention is made of the very useful practice of making small punctures in Wolfe grafts to ensure easy egress of blood or serum which may collect under them even in the presence of elaborate pressure dressing. It is difficult to understand why the author, strongly advocating the Stent mould as a means of keeping the full-thickness graft in apposition with its bed, gives preference to other forms of dressing for Thiersch grafts. The erroneous impression is given that the Stent mould, now so commonly used for the latter, has the disadvantage of producing temporary depression of the grafted area. The amount of depression depends surely upon the depth of preliminary excision, whatever form of graft or method of application is employed. It will not be generally agreed that the lower leg and lower thigh are "convenient" sites for the preparation of tubed pedicle flaps, for the skin in these regions is much too limited to allow of closure of the defect produced by the raising of a flap of useful proportions. The author states that one end of a tubed pedicle flap may be divided and implanted after a wait of ten days; such an early shift will often end in failure, and in the one successful case reported later in the work a delay of three weeks was made at this stage.

Case records, illustrated by excellent photographs, occupy two-thirds of the book. These indicate clearly the early results obtained in the treatment of leg ulcers. The author was unable to observe his cases over a long period, but the reports (rather lacking in detail), obtained two years after grafting, suggest that in the majority so treated these good results were maintained. This is contrary to the more usual experience in such cases, initial success being followed, after satisfactory periods of even a year or more, by partial or complete breakdown of the grafted area for no apparent cause other than bad local circulatory conditions, in the presence of which slight trauma is sufficient to set up extensive phlebitis. In this connexion it is surprising to find no mention of treatment of neighbouring varicose veins, an auxiliary therapy which undoubtedly improves the local nutritional conditions and so assists in the establishment of the permanence of the grafts.

The essential point in the technique described is the free excision of the ulcer-bearing area. In so far as Mr. Christie's small book encourages efficiency in this direction by giving the surgeon confidence in his ability to cover the resulting extensive raw surface, it will attain its laudable object.

PSYCHOTHERAPY

Modern Psychotherapy,[4] by Dr. EMANUEL MILLER, may be recommended as an admirable introduction to an involved and difficult subject. The author, who has at his command a lucid and agile literary style, avoids unnecessary technicalities, writes impartially, and makes no excessive claims for the various methods of treatment which are the subject of discussion. Psychotherapy is here concisely defined as any form of healing which has as its object treatment by mental influence. By this definition it is intended to bring home to the student the fact that within the whole range of medicine, in both physical and mental disorders, psychological factors of varying degrees of intensity are involved. As the author observes, whether the case be one of manic-depressive psychosis or the amputation of a limb, a psychological attitude must be adopted not only by the psychiatrist in the one instance, but by the surgeon in the other. The various shades of medical attitude are determined more by the degree in which psychology is involved than by the physical remedies used. In successive chapters the author describes the general principles of psychotherapy; the analytic methods of Freud, Jung, and Adler; methods of suggestion; the applications of psychotherapy in the neuroses, and in drug addiction; early treatment and prevention; and, finally, psychotherapy in organic disease. The book includes a useful glossary of terms not fully defined in the text.

MALFORMATIONS OF THE JAWS AND TEETH

A freely illustrated book on this subject[5] is the joint work of Dr. E. HEREST, who deals with malformations of the jaws, and Professor M. APFELSTAEDT, who deals with malformations of the teeth. The authors' aim has been to cover as much ground as possible while keeping the work within moderate compass, and to arouse fresh

[4] *Modern Psychotherapy*. By Emanuel Miller, M.R.C.S., L.R.C.P., D.T.M. The Modern Treatment Series. London: J. Cape Ltd. 1930. (Pp. 131. 5s. net.)

[5] *Malformations of the Jaws and Teeth*. By Dr. Emil Herlst and Dr. Max Apffelstaedt. Oxford Medical Publications. London: Milford, Oxford University Press. 1930. (Pp. xii + 320; 298 figures. 25s. net.)

interest in teratology. Consequently, descriptive letterpress has been reduced to a minimum. The whole range of malformations, from double formations (adherent twins), through epignathism, etc., to such minute deformations as enamel nodules on the roots of tooth, is considered, and an attempt made to clarify a seemingly incoherent mass of material. In this respect we think the section on malformations of the jaws has achieved the greater success. This opinion, however, is not to be taken as meaning that the second part has less scientific interest. It means rather that the correct placing of so small a thing as, for example, a peg-shaped tooth, is still open to doubt, and that the impartiality with which the authors have quoted all shades of opinion whets curiosity rather than satisfies doubt. The interest of the general body of dental surgeons, indeed, will probably be centred on this latter part of the book, since it includes the abnormalities more commonly met with in daily practice, and indicates the possibility of reducing to order what seems to be but a confused mass of curiosities. For our part we think the few pages devoted to torus palatinus and to paragnathus of particular interest; while Bauer's case of rootless dentition deserves all the attention devoted to it. Hypoplasia of teeth we think inadequately treated, and it may be doubted whether " the fight for space " deserves all the credit it gets in the production of malformations. The authors have drawn freely (and with due acknowledgement) on the works of others to supplement their own by no means inconsiderable experience, and have produced a book which should, as they hope, stimulate others to record and ponder—but especially to record fully and with scrupulous care.

NOTES ON BOOKS

The third edition of BEESLY and JOHNSTON'S *Manual of Surgical Anatomy*[6] was reviewed at some length in our issue of September 17th, 1927 (p. 496). A revised edition has recently appeared, but, apart from the needed correction of two figures of the interior of the knee-joint, we have been unable to detect any change worthy of notice.

In *Recent Advances in Entomology*[7] Dr. IMMS gives a readable and accurate account of some of the modern developments in this branch of zoology. Its contents, however, are mostly outside the scope of medical entomology. The chapters on parasitism and biological control, although referring to parasites of insects and biological control of insects harmful to agriculture and forestry, are not without their human interest, however, because the methods adopted for controlling these groups may ultimately be employed in a similar way against insects harmful to man himself.

In *Athletics in Education*[8] two American professors of physical education develop the view that all forms of athletics have a part in physical education, and condemn " sport for sport's sake " as the worst dilettantism. It is evident that the American attitude towards athletic sports, if this book represents it fairly, differs from that in this country. In adopting British athletics North America seems to have modified them, turning games into a serious business, to the detriment, no doubt, of the games, but tending to produce a high degree of excellence in the players. Originally, athletics in American universities were started by students and frowned on by the authorities ; but now the view is expressed in this book that physical education should not be controlled by the students themselves, and diagrams are given showing an elaborate organization under a director. The authors must not, however, be misrepresented, for they are genuinely anxious to get the best out of athletics in every way. The first hundred pages deal in a general manner with athletics in schools and colleges, the next two hundred pages contain systematic directions about their organization, and a chapter is devoted to their medical control. Finally, there is an annotated bibliography of nearly a hundred pages.

The *Minutes of the General Medical Council and of its Various Committees* for the year 1930 have been published, with twenty-one appendices, in a volume which includes reports of the two sessions of the General Medical Council, of its Executive and Dental Committees, and of the meetings of the English, Scottish, and Irish Branch Councils. The appendices comprise reports of the Public Health, Pharmacopoeia, Education, Examination, Dental Education, and Examination Committees, and a memorandum by the Registrar in regard to the history of the inquiry into the standard of Indian medical degrees. The *General Index* to the Minutes of the Council and of its Executive and Dental Executive Committees, and of the three Branch Councils, from 1903 to 1930, relating to volumes xl to lxvii, follows the plan of the previous issue.

Crime as Destiny,[9] with a foreword by Mr. J. B. S. HALDANE, is a translation of Dr. Johannes Lange's monograph, *Verbrechen als Schicksal*, which was reviewed in these columns on April 27th, 1929 (p. 770).

[6] *A Manual of Surgical Anatomy*. By Lewis Beesly, F.R.C.S.Ed., and T. B. Johnston, M.B., Ch.B. Third edition, revised. Oxford Medical Publications. London: Milford, Oxford University Press. 1930. (Pp. xvi + 563 ; 166 figures. 18s. net.)

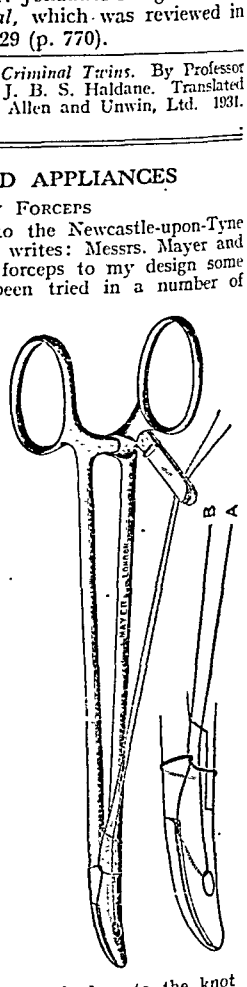
PREPARATIONS AND APPLIANCES

TONSIL ARTERY FORCEPS

Mr. W. J. HARRISON (surgeon to the Newcastle-upon-Tyne Throat, Nose, and Ear Hospital) writes: Messrs. Mayer and Phelps made some tonsil artery forceps to my design some months ago. They have now been tried in a number of cases, and I find that ligaturing the vessels is made easier and quicker by their use. As the illustration shows, the blades have a well-marked slope from the lock to the tip, which helps the ligature to slip over the end. The slight curve on the flat facilitates picking up the bleeding points in the more inaccessible parts, and by depressing the handles the point can be elevated, which often helps in ligaturing the vessel. There is a fenestration in one blade, and the convex sides of both are sufficiently apart from each other to allow a ligature of No. 3 silk to move freely between them when the forceps are closed. This aperture reaches more closely to the tip than is shown in the illustration.



The illustration shows how one end of the ligature is passed through the fenestration out through the convex side of the blades, and a half-hitch surrounding the forceps and the part A of the ligature made before the two ends are secured in the holder near the handles. This saves the trouble of manipulating the knot down the handles. To tie, both ends are released and the knot tightened and manipulated over the tip, either by the finger, or by the end, B, being grasped close to the knot in straight forceps. When the vessel is secured the forceps are opened and gently withdrawn, thus freeing the part A, when the knot is completed. With ordinary care it is very seldom that the vessel is not firmly secured at the first attempt, wherever situated.

RECENT METHODS OF SEWAGE TREATMENT

PAPER BY DR. WILLIAM BUTLER

At a sessional meeting of the Royal Sanitary Institute, held in London on February 10th, a paper on recent methods of sewage treatment was read by Dr. William Butler, Medical Officer (General Purposes) London County Council. This account of methods of treatment and of the ways in which purification was believed to occur was, he said, based on an investigation, extending over some years, which he had had the privilege of directing. Treatment on land was perhaps the earliest instance of natural purification of sewage. Long before it became purposive it must have occurred, and its early use was but an application of natural occurrence. The biological filters—contact beds, percolating filters, mechanical intermittent sprinklers, etc.—were later devices for intensification, on smaller areas, of natural purification.

Principles of Purification

Two main conditions were recognized as essential in all these various methods of application of natural processes: (1) a plentiful supply of atmospheric oxygen freely dispersed throughout the whole volume of the liquid treated, and (2) exposure under this condition to the humus, coating the aggregates, whether of soil or filter beds. A great stride in intensification of treatment was made when Dr. Fowler dispensed with the aggregates and dispersed the free humus—which became known, unfortunately, as "activated sludge"—throughout the liquid, into which air was directly diffused by pumping. The same kind and degree of purification was obtained as by land treatment or biological filter treatment, but it was possible by this means to deal with a much larger volume of sewage in any given unit of time and space. The change of venue from filtration through soil or solid aggregates to natural purificatory processes conducted exclusively in a liquid medium did not mean change in any essential features of the processes. In the main these were, as they must always be, oxidation of the organic contents of the sewage by "wet combustion" effected by natural agents.

If a crude sewage from which its grosser suspended matters had been gravitationally deposited was mixed with a suitable free humus in the form known as activated sludge and the mixture was well shaken for a few minutes, it would be found that an extraordinary change had in this short time been brought about. The sewage so treated had become inoffensive, and would remain so indefinitely, whether, after decanting from the humus which had been allowed to separate, it was left exposed to the open air, or was sealed in a closed vessel and incubated at 80° F. for several days.

Two important features of the changes were: (*a*) establishment in the treated liquid of nitrogen oxidation, and (*b*) reduction of the colloidal content. While far from being exhaustive, the initiation of these processes appeared to secure a sufficient degree of stability in the resulting inoffensive liquid to permit the continuing oxidizing processes to proceed without the supervention in ordinary circumstances of putrefactive changes. Given a humus capable under suitable conditions of exhibiting rapid oxidizing activity in the medium with which it was intermixed, and at the same time of precipitating from this medium the unstable organic colloidal content, two essential aims in sewage purification had been attained. A humus capable of such activity was a living substance. Its chemical and physical functioning was at once and completely destroyed if by chemical or physical agents it was killed. Success depended upon maintaining the humus in a high state of functional activity, upon sustained and intimate admixture of the sewage and humus throughout the period of contact, upon facilities for maximum absorption of oxygen from the air by constant and rapid change of liquid at the air-sewage interface, upon the use of a sewage from which the grosser suspended matters had been previously deposited, and upon the use of the device for supplementing oxygen absorption by means of the continuously renewed air cushion in the lower channels.

Application of Principles

Different forms of plant in which these principles were applied had been investigated, and there emerged ultimately a double channel in two tiers separated by a septum with intercommunicating ports along which the mixture of sedimented sewage and humus was mechanically propelled. The purpose of this device was, in effect, to interrupt at desired intervals the septum separating the upper from the lower chambers, and to interpose in continuity with the ends of the interrupted septum what were virtually the blades of a propeller so arranged that the respective channels intercommunicated without disturbing the parallelism of the walls of the channels and with continuous separation of the channel contents. By the admission of air to the lower channel near to the commencement of the return flow, and the provision of fillets at either end of the false bottom, a cushion of air was continuously displaced and renewed throughout the course of the false bottom. The device was found, when used in conjunction with air-diffusion tanks for regenerating the humus, to yield results which were a great advance in efficiency on any of the more recent methods of treatment with which they experimented. Upon the evidence submitted to it, the London County Council decided to install a large plant of this type for the treatment of London sewage, and it was now in course of construction at the Southern outfall.

A Physiological Analogy

Concluding, Dr. Butler said that in the form it had assumed in this later development of sewage treatment, a structure had gradually been evolved which functioned in a manner not remotely removed from that of the circulatory and respiratory systems of the higher vertebrates. The circulating fluid propelled along the channels represented, however, not merely the blood, but the tissues. It contained an analogue of the red corpuscles in the living humus, which moved freely in intimate admixture with the circulating medium. If not directly an oxygen carrier like the haemoglobin of the red corpuscles, this humus was yet the agent by which the oxygen of the air was utilized in burning up the waste products contained in sewage liquor. These waste products, mainly the colloids of sewage, were the analogues of those of tissue metabolism, and, when brought into intimate contact with the circulating humus, were removed and ultimately oxidized to a final mineral product. The respiratory apparatus by which the interchange of dissolved gases with those of atmospheric air was effected was less highly organized and differentiated than a mammalian or avian lung. But in the diffusion tanks for reconditioning of the humus, in the exposure to the air at the air-sewage interface of ever-renewed films of deoxygenated liquor in the channels, and above all in the varying pressures to which the gases were subjected, alternately raised in the imprisoned cushion and lowered on release at the portals of the septum, a mechanism might, without straining the analogy, be discovered corresponding to the apparatus by which the biophysical and

biochemical processes of respiration were conducted. That this should be so was in accord with the nature of things; for, after all, the final disintegration of waste organic matter was but a later phase in a process that began in metabolic changes in living tissue. The waste matters eliminated from the living corpuscles were a prey to oxidative chemical processes which, commencing at their birth, were continued through their intra-corporeal journeyings, and terminated only in the final mineralization of complete combustion.

DRUG CONTROL IN INDIA

BY

J. C. DAVID, M.B., B.S.MADRAS

A Drugs Inquiry Committee has been recently appointed by the Government of India with the following terms of reference:

1. To inquire into the extent to which drugs and chemicals of impure quality or defective strength, particularly those recognized by the *British Pharmacopoeia*, are imported, manufactured, or sold in British India, and the necessity in the public interest of controlling such an important manufacture and sale, and to make recommendations.

2. To report how far the recommendations made in (1) may be extended to known and approved medicinal preparations other than those referred to above, and to medicines made from indigenous drugs and chemicals.

3. To inquire into the necessity of legislation to restrict the profession of pharmacy to duly qualified persons, and to make recommendations.

The chairman of this committee is Lieut.-Colonel R. N. Chopra, M.A., M.D., I.M.S., professor of pharmacology at the Calcutta School of Tropical Medicine. Colonel Chopra has been doing pioneer work during the past eight years, carrying on much painstaking and often fruitless research on the indigenous drugs of India, and has been closely studying the problems that come within the purview of the terms of reference of this inquiry. In the course of his presidential address, delivered to the Medical Section of the Indian Science Congress held in Lahore in January, 1927, he advocated legislation in India on the lines of the British Therapeutic Substances Act as a means of protection against the indigenous production of patent and other medicines.

Preparation and Sale of Medicines in India

At present, while in most other countries regulations regarding the preparation and sale of medicines are very strict, no standard of any kind whatever is imposed in India. Many manufacturers in that country produce articles which have a very slight resemblance to the standard or genuine article, so that firms anxious to produce only reputable goods cannot compete. While firms manufacturing pharmaceutical products are increasing in number, few care to have them properly standardized. Some of these preparations have time and again been found by Colonel Chopra to have great variation in their strength. The writer was told by a representative of a well-known firm of manufacturing pharmacists in Madras that it could not afford to have its products biologically assayed because of unhealthy competition. An inquiry by excise authorities into the causes of decreased sale of rectified spirits elicited the fact that in many cases alcohol was not being used in the quantities necessary to produce the standard articles. Large quantities of medicines are sold in tablet form—for example, a 5 grain tablet of quinine was found to consist of only 1 grain of quinine and 4 grains of starch or other inert matter. Here, perhaps, we have the explanation of the so-called "quinine-resistant forms of malaria"! It is not long since Colonel Gidney, I.M.S.(ret.), called attention in the Assembly to the disgraceful traffic in adulterated quinine. Sir P. C. Ray, the well-known Calcutta chemist, once purchased several samples of santonine all over the country and found gross adulteration—in one to the extent of 90 per cent. Not only are galenicals and other pharmacopoeial preparations manufactured by Indian firms, but attempts are being made to prepare some of the biological products, such as gland extracts, vaccines, serums, etc. Moreover, a number of potent organic compounds of antimony have been introduced by some manufacturing firms in Calcutta, and are being used extensively as intravenous injections by practitioners. No control whatsoever is exercised by the State over these potent compounds.

Deterioration of Imported Drugs

With regard to imported drugs, the climatic conditions of India have to be taken into account. Deterioration is an important factor, and the keeping properties of organic arsenicals, insulin, and a number of other potent remedies, when exposed to tropical climates, have not yet been determined. Much work has been done in this direction at the Calcutta School of Tropical Medicine, where facilities also exist for the bio-assay of pharmaceutical products, but few manufacturing concerns take advantage of them under present conditions.

Remedies of Indigenous Systems of Medicine

Another great problem is presented by the remedies—which are legion—of the indigenous "Ayurvedic" and "Unani" systems of medicine. To lay down rules with regard to their purity, etc., while their composition as well as their efficacy is unknown and untried, is impossible. To sift the possibly useful drugs from a host of remedies, to every one of which great curative power is attributed, is indeed a Herculean task. Colonel Chopra and his staff of research workers have been engaged in this subject for the past eight or nine years, but of the drugs investigated by them, barely two, or perhaps three, have so far proved to be of any clinical use. There is little doubt, however, that this is the best method of attacking the problem. The Governments of Bombay and Madras have now established research units for this purpose, the former at the Parel Laboratory, Bombay, and the latter in connexion with the pharmacological department of the Madras Medical College.

Training of Pharmaceutical Chemists

Closely related to these problems is the question of training pharmaceutical chemists. At present, only one institution—namely the Madras Medical College—trains candidates in a two years' course for the Government chemist and druggist diploma. But even this course, meagre as it is, is not popular, and there have been few candidates in recent years. This is not surprising, because anyone, even without any training, may start business as a pharmaceutical chemist, provided he has the small amount of capital necessary to furnish the shop. There is practically no check on this profession except that exercised by the Excise Department in the sale of dangerous drugs, such as morphine and cocaine. The writer computed that out of a total of about one hundred chemists and druggists in Madras city during 1929, barely eight were in any way trained for the profession. A Pharmaceutical Society of India exists, but it cannot be compared to the society in Britain. It is still in its infancy, being the result of the efforts of a few enthusiasts, who are, as yet, like sheep without shepherds.

Under these circumstances it is obvious that the committee has been appointed none too soon.

British Medical Journal

SATURDAY, FEBRUARY 21st, 1931

THE PRIMARY SCHOOL CHILD

On January 15th, 1927, we described and commented upon the report of the Consultative Committee to the Board of Education, entitled *The Education of the Adolescent* (since commonly known as the Hadow Report), which recommended the regrading of public education in two stages: primary education up to the age of 11 years or so, and post-primary education beyond that age in varying types of schools. Our comment was mainly directed to show that education and health are largely but different aspects of the same subject, that the work of the medical profession and the work of the teaching profession and of educational administrators must be intimately associated, and that this should involve a broad acquaintance of each with the aims and problems of the others. If these truths were illustrated by the proposals made at that time and embodied in the Hadow Report, they are even more fully and directly applicable to a consequential report of the Consultative Committee now published under the title of *The Primary School*.[1] Under the new grading, education must be regarded as an organic whole from 5 years of age to 11 without any serious break. Yet it may well have two phases—that in the infant school up to 7 years of age, and that in the junior or primary school from 7 years to 11 years. It is to the question of the propriety of these changes at 7 years and at 11 years, and to the character and conditions of education between these ages, that the present report is mainly directed. Of much medical importance are Chapters II and III (with the corresponding appendices by Dr. H. A. Harris, assistant professor of anatomy, University College, London, and Dr. Cyril Burt, psychologist to the London County Council), on the physical and mental development of children between the ages of 7 and 11; and Chapter VI, on retarded children. Moreover, parts of other chapters have direct medical interest, and the whole report will repay close attention.

In some respects the parts of the report that we have named present a challenge to the clinician as well as to the anatomist, the physiologist, the psychologist, and the teacher, to undertake further observations on the physical and mental condition and growth of children between the ages in question. These matters have been studied fairly extensively and intensively with regard to the very young child and the adolescent, but the ages between have been relatively neglected. Dr. Harris and Dr. Burt here present us with the picture of four types or aspects of growth—the skeletal, the neural, the lymphoid, the genital—though recognizing that these are "at best only crude representations of the complexity of the processes actually involved"; of successive cycles of general growth in children, the "springing-up" periods and the corresponding "filling-out" periods; of four types of child organism, hypersthenic, sthenic, hyposthenic, and asthenic. It is pointed out that mass statistics are apt to prove fallacious in practice; that curves of height and weight give but an imperfect picture of the complex patterns of growth in the different systems of the human body; that, though there is a definite limit to the amount of change that can be impressed on a growing child, the period of consolidation between the ages of 7 and 11 may be regarded as affording the best opportunity for remedying past defects of development, and preparing the organism to meet the demands of puberty. The necessity for great care in submitting boys or girls to heavy or sustained muscular effort is enforced by describing the development of the two sets of composite bones, the scapula and the os innominatum, and by the fact that serious illnesses are recorded on the bones as lines of arrested growth. When growth is resumed after the removal of the harmful conditions these appear as scars on the bone. To urge young children to work hard before they have completely recovered from illness is therefore a grave error.

The rapidity of growth of the brain and the normally great development of the pyramidal outer cell layer of the cortex are noted. When the infant is 2 years old the brain has attained 60 per cent. of its normal size, and by the age of 7 it has almost reached adult size. The pyramidal layer increases in thickness from birth to maturity by more than 50 per cent., but not uniformly in all regions of the brain. These facts make it highly important to study cerebral changes more intensively. Really very little is known about such changes between early childhood and adolescence. It is possible that the laminae of the developing cortex are far more susceptible to malnutrition and disease than is at present admitted, and in particular we need to know whether anatomical age changes are connected with the acquisition of new mental processes and how far such processes, once lost or impaired, can be resumed. The bearing of such researches upon the pedagogical problems of the normal child and upon the classification of, and methods of dealing with, retarded children is obvious, and may be very far-reaching. It seems to be a fact that teachers have somewhat misunderstood the psychology of the child between 7 and 11, and Dr. Burt's memorandum in the report is of fascinating interest, and cannot well be summarized. He deals with sensory capacities, with the working contents of the child's mind, his imagery and ideas, his reasoning, his emotional qualities, and his aesthetic development. Dr. Burt's conclusions with regard to the various forms of reasoning power seem particularly important, but throughout he brings to light a number of general misconceptions, and makes suggestions which ought to be

[1] Board of Education. Report of the Consultative Committee on the Primary School. London: H.M. Stationery Office. 1931. (2s. 6d. net.)

of practical use, not only to the teacher, but to the school doctor and to the private practitioner.

Recent psychological researches, it is said, indicate that as regards innate mental capacity the differences between individual children are unexpectedly wide, and remain fairly constant throughout school life. By the age of 10 they cover a range equivalent to more than ten years of mental growth—that is, the dullest pupils of that age may have a mental age of less than 5, while the most gifted may have a mental age of more than 15. But towards the end of the primary stage a large majority, some 80 per cent., fall within a mental range of about three years. The exceptional children will comprise about 10 per cent. who are unusually bright and about the same proportion who are definitely retarded. The latter may be conveniently classified into three groups: mentally defective, more retarded, less retarded. In the *Journal* of April 27th, 1929, we discussed the report and proposals of the Joint Committee on Mental Deficiency. Though the members of the Consultative Committee are careful to say that they are in agreement with the Joint Committee's proposals, they really seem to differ from them in at least one important respect. They suggest that, instead of dealing with all these retarded children as one group, the mentally defective children and the more retarded children should be taught in special schools, wherever possible; those of the less retarded group being retained in special classes of the primary school. They reinforce, however, the now common demand that no child should have to be medically certified as mentally deficient in order that he may receive the kind of education appropriate to his capacity.

UNIVERSITY REPRESENTATION IN PARLIAMENT

At its last meeting the Council of the British Medical Association passed the following resolution: "While expressing no opinion as to the merits of the Bill as a whole, the Council is opposed to the clause in the Electoral Reform Bill which abolishes the university franchise." The first phrase in this resolution was intended to emphasize the fact that the Association and the Council have no concern with party politics, and cannot properly take any action with a view to influencing the continued existence of any particular Government or the attainment of power or office by any alternative Government. There have, of course, been many occasions on which detailed proposals in Government Bills and other measures before Parliament have been the subject of criticism, opposition, and proposed amendment by the Association in the interest of the public health, of the advancement of science, or even of the medical profession itself when such proposals have been contrary to the public good. This freedom of action, especially where no vital point involving the existence of the Government is concerned, is very valuable. On the present occasion the Council, being appealed to by a committee representative of the universities and of many learned societies, felt that it should support the continuance of university representation in Parliament. Such representation, in times past, has proved to be a very convenient and appropriate channel through which the views of the medical profession have been presented for consideration to Parliament, and this not mainly by members of the profession itself. Without it such opportunities would be severely curtailed and might disappear altogether.

The British system of government rests fundamentally upon public discussion of affairs by representative persons. It is undoubtedly essential to the complete success of such a system that these representations should broadly reflect the opinions of a wide electorate, and should be able adequately to voice all the greater interests of our national life. Many believe that this cannot be securely attained except by means of the device known as proportional representation; and it is admitted that under the present system of constituencies and of voting the House of Commons may be a very imperfect mirror of public opinion. University representation, under this system, provides a useful though subsidiary means of rectifying the mirror. Under present conditions it is true to say that, in territorial constituencies, a candidate of independent mind who is unable to enrol himself as a member of one of the great organized political parties has but a negligible chance of being elected. Yet there are many hundreds of thousands of electors who would desire to have such a representative, and it is only through the university franchise that an approximation to relative independence has been provided for. It is true that the opportunities have not been fully used, but, if continued, there are signs that they will be taken advantage of much more extensively in the future.

Again, an outcome of the present system, though not one it was designed to achieve, is that important trades and industries are able to control the representation of a number of constituencies. Those engaged in, connected with, or dependent upon such industries are largely localized in certain districts. This is not to be deprecated. It is fortunate that in this way the wider interests of those associated with such occupations throughout the country secure attention apart from purely local considerations, and that industrial organizations can thus exercise great influence on public affairs. Apart from university representation there is no such opportunity for the great professions or for scholarship and learning in general. Yet it will scarcely be denied that these should be sure of some modest place, as such, in any assembly which purports to be properly representative. It cannot now be said truthfully that the university electorates consist of very restricted social classes or of those with a narrow and purely favourable experience of life. They certainly do not represent wealth; indeed, they contain a large and rapidly increasing proportion of men and women who received their early education in the public elementary schools. Incidentally, it is one of the minor advantages

of the university franchise that it alone provides a means of representation for a considerable number of those who are engaged abroad in the diplomatic and other national services.

In view of the facts that university representation has existed as part of the English constitution for more than three hundred years without any obvious disadvantage, and that since the war it has been developed and increased by common consent as part of an inter-party agreement, no serious changes in its character appear to be required. There are, however, at least two suggested modifications which might perhaps be considered if they would make the retention of the university franchise more acceptable to some. One of these is that the universities should be combined into a single constituency, with a somewhat reduced total number of members elected by proportional representation. The other is that, if "one man, one vote" is to be erected into a principle, those whose names are on both a local and a university roll of electors should be allowed to exercise only one of these votes at their choice. A change which, in our opinion, and that of many others, is highly desirable, though this cannot be the subject of legislation, is that there should be no attempt at party political organization within such electorates, and that independent choice on non-party grounds should be encouraged.

In accordance with the resolution of the Council, it is desired that those members of the British Medical Association who are convinced that these arguments have weight should inform their parliamentary representative of this fact without delay.

THE DOMAIN OF ORTHOPAEDIC SURGERY

The instructive presidential address by Sir Robert Jones, delivered before the International Society of Orthopaedic Surgery in Paris, and published in our present issue, coming from such a distinguished source, cannot fail to interest surgeons and students of the history of surgery. It combines a brief summary of what is known about orthopaedic surgery in ancient times with a sketch of recent developments, and a kind of apologia for the existence of this special branch of surgery. Hippocrates, Pasicrates, and Heliodorus long ago recorded their knowledge of certain deformities and had ideas about their treatment, yet we can hardly believe that with the means at his disposal even Hippocrates could have treated with success a congenitally dislocated hip. Diagnosis is one thing, successful treatment another. Some passages of Sir Robert Jones's address were obviously intended to inform a Continental audience of what has been, and is being, done in this country, for the triumphant history of the Military Orthopaedic Hospitals (afterwards renamed Special Surgical Hospitals) and the progress of the county schemes for the cure of cripples are well known here, and the latter have been often advocated in our pages. The ground gained in wartime has not been lost in peace. These hospitals provided almost a revelation of what could be done for the treatment of gunshot fractures, the prevention and cure of deformities, and the rehabilitation and training of crippled limbs. The Thomas splint, properly used, proved to be one of the most beneficent life-saving devices ever employed on or near the field of battle. The lessons of the war have not been forgotten, but are applied in our civil hospitals to the problems raised by industrial and locomotive accidents.

As the president pointed out, the practice of orthopaedic surgery is by no means limited to orthopaedic specialists, for in France those who undertake it are also general surgeons, and in the past in this country distinguished general surgeons such as Macewen have contributed to its progress in no small degree. Specialism is not now on its defence as it was at the end of the last century. The vast enlargement of the field of surgery has rendered subdivision necessary and tolerable. A reasonable plea on behalf of some specialties has been that special skill can only be acquired by special experience, and that that experience can only be obtained by concentration of the surgeon's time and attention on the subject. But Sir Robert Jones would have every orthopaedic surgeon not only an all-round practitioner, but a highly skilled operating surgeon; his ideal is the general surgeon who applies himself to a special branch of his art. This is perhaps a counsel of perfection, and its adoption would require a very large number of first-rate general surgeons concentrating on orthopaedics if the treatment of fractures, recent and long-standing, of deformities of the extremities and spine, of diseases, derangements, and disabilities of the joints, including the spine, and of injuries of peripheral nerves, are to be treated orthopaedically. All these conditions were cared for during and after the war in the Special Surgical Hospitals under the direction of Sir Robert Jones.

The eighteenth-century Paris physician Nicolas André from the title of whose book the word "orthopaedic" originated, unwittingly laid a stumbling-block in the way of the layman of inquiring mind, and of the student of surgical nomenclature. Other specialties may have names of Greek derivation of greater length and more syllables, but the layman who asks, "What is ophthalmology?" is easily answered by "Eye surgery," as he who inquires about laryngology is satisfied to be told "Throat surgery"—and so with the other specialties. But unhappily, with orthopaedics the case is different. At one time, as Sir Robert says, it was restricted to the treatment, without open wound, of a few deformities; but even then its definition was difficult, and those who tried to persuade the public that "paedic" had no special reference to the feet and was not formed by a misspelling of a Greek or a Latin word for the foot, got small reward for their pains. All attempts to provide a logical and exact definition of what was included in orthopaedic surgery failed, and attempts to define the present greatly

extended scope in a few words have equally been unsuccessful. Perhaps the nearest to success is that which claims that orthopaedic surgery is "the surgery of the human body, excluding its cavities and the organs of special sense." This at first sight may seem extravagant, but careful consideration will show that it includes nothing that has not been claimed by orthopaedic authorities. So wide-reaching are these claims that we have even heard it suggested that in the not far distant future orthopaedic surgery will become known as "surgery," and the abdomen and the brain and the special senses will become tolerated specialties. However that may be, in the United States there are already signs that the term "orthopaedic" may fall into disuse. A few years ago the *American Journal of Orthopaedic Surgery*, the official organ of the American Orthopaedic Association, changed its name to that of the *Journal of Bone and Joint Surgery*, and some American orthopaedists no longer so describe themselves, but indicate their range of work in some such terms as "Practice limited to surgery of bones, joints, and deformities."

AN INSTITUTE FOR SURGICAL RESEARCH

As briefly recorded in our university and college news this week, the Council of the Royal College of Surgeons of England at its last meeting accepted a munificent offer from Mr. George Buckston Browne, F.R.C.S., to build and endow an institution of surgical biological research, on an estate adjoining Darwin's old home at Downe, in Kent, which, it will be remembered, he gave two years ago to the British Association in custody for the nation. In his letter to Lord Moynihan, President of the College, Mr. Buckston Browne expressed his belief that those who have added, or are adding, to the science and art of surgery, are the greatest of all benefactors to the human race and to the domesticated animal kingdom. Hence, at the end of a long surgical life, he wishes to facilitate the labours of those, particularly young surgeons, who are willing to devote time to surgical observation and research. The institution he has in mind would be an extension of the scheme which the Council has already established by the equipment of laboratories in direct connexion with its Hunterian Museum in Lincoln's Inn Fields. The land offered by him to the College as a gift provides, he believes, an ideal site for a biological farm, where research workers can study living animals, just as John Hunter did at his farm at Earl's Court. "There is ample accommodation and pasturage for animals, and its intimate association with Darwin should provide inspiration for those who desire to follow in the traditions of Hunter." For the time being Mr. Buckston Browne suggests a moderate equipment, just enough for present requirements, and he thinks that the following initial provisions would suffice: (1) three or four laboratories where investigations can be made under the best conditions, or where living animals can be closely observed and cared for; (2) houses for animals; (3) accommodation for the chief attendant—one skilled in laboratory methods; (4) accommodation for a stockman to look after and feed the animals; (5) hostel accommodation for those working in the institution, should they wish to carry on continuous study. The detailed work of examining the results would be carried out in the laboratories of the Royal College of Surgeons, and therefore pathological laboratories at the Downe Institution would be unnecessary. The initial stages of layout and equipment would be directed by the Conservator of the Museum, Sir Arthur Keith. The closing passage of Mr. Buckston Browne's letter runs as follows: "I am prepared to give you £50,000; and I will add further sums from time to time until my gift—including the cost of the land and such interest as may accrue from money lying in your hands—shall altogether amount to £100,000. If this sum be not reached before I die, I shall arrange that my estate makes good the balance due." The Council of the College, deeply impressed with Mr. Buckston Browne's great liberality, resolved, by a unanimous vote, to undertake responsibility for the proposed institution, subject to an approved settlement under a trust deed.

THALLIUM AND ITS RISKS

A very interesting case of thallium poisoning was recently reported by Dr. John Lansbury at a staff meeting of the Mayo Clinic. He was called to see in consultation a lady, aged 38, with severe abdominal pain and a slight maculo-papular eruption. The skin of her legs was warm and scaly, and so rough that it suggested ichthyosis. On the feet were dry calluses, which were beginning to peel. The hair was loose and easily pulled out. Five days later the unhappy patien had become almost bald, except for a thin fring round the margin of the scalp. The body hair als fell out to some extent, but the eyebrows and eyelashe were not affected. Later the pain subsided, the textur and functions of the skin returned to normal, and th hair began to grow again. Struck by the way in whic the skin had been affected, and especially by th remarkable loss of hair, Dr. Lansbury at once suggeste the possibility that this was a case of thallium poisoning and his diagnosis was amply confirmed by the discover that for about five weeks the patient had been usin a depilatory cream on her face. This cosmetic wa analysed and found to contain a large percentage o thallium, but no lead; the absence of lead is noteworth in view of the severe colic from which the patien suffered. The poisonous qualities of thallium have beer known ever since the element was first discovered i 1861, and many attempts to employ it for therapeuti purposes have been associated with accidents to th patient which, until recently, have prevented its accept ance as a remedy, although tentatively tried for severa purposes. These drawbacks have now, it is true, beer so successfully overcome that within recent year many thousands of children have been treated for ring worm of the scalp by the single dose method. It mus be admitted, however, that even this is not withou its dangers, especially to children over the age o 6 years, and a good many cases of poisoning, some fatal, have been recorded; but besides the case mentioned above we have only heard of one other (reported by Ramond) in which thallium, employed in the form of a cream for the treatment of hypertrichosis, has been followed by toxic sequels. The pharmacology of thallium has been investigated by Professor W. E. Dixon, who has pointed out that the chief characteristic

of its action, shared by no other metal, is its effect on the autonomic nervous system. Just as strychnine encourages the passage of reflex action through the spinal cord, so thallium appears to facilitate the passage of stimuli in connexion with the autonomic nervous system. The production of alopecia, which is so remarkable an effect of the administration of thallium, is unique in pharmacology; there is no other substance whatever, the absorption of which can do the same. According to Professor Dixon, thallium rubbed into the skin does not depilate locally; it is only after absorption that the metal affects the hair. If this be so—and there is no reason to doubt it—the employment of thallium in depilatory creams is highly dangerous; for the margin between the depilatory dose and the toxic dose is extremely small, and therefore the employment of thallium for this purpose should be strictly forbidden. The Board of Education has already interdicted its use in the treatment of ringworm in school children.

NEW X-RAY UNIT FOR AMBULANCE WORK

The Home Service Ambulance Committee of the Joint Council of the Order of St. John and the British Red Cross Society recently gave a demonstration, which was attended by representatives of the War Office and the London County Council, of a new high-power mobile *x*-ray unit to meet the demands of the ambulance radiographic service which the committee undertakes. The object of this service is to provide for the radiographic examination of patients who are confined to bed suffering perhaps from some deep fracture or acute condition, which makes it inadvisable for them to be transported to the *x*-ray department of a hospital or to a radiologist's consulting rooms. Many of the smaller hospitals whose finances do not permit of the installation of satisfactory apparatus prefer to take advantage of this service rather than have smaller equipment, which would not meet the demands of the exceptional case. The service is primarily designed for work in and around London, though journeys to the North of England have been undertaken. It is a necessity in any such arrangement that the installation, while mobile, shall be capable of doing work as varied and as accurate as the best stationary equipment. The original unit employed was one built by the Joint War Committee of the Order of St. John and the Red Cross Society for use on the Italian front. It proved to be too cumbersome, and was modified in some respects, but in course of time this type of set—a 16-inch coil installation—became obsolete. Tests were then made with a 30 ma. transformer set, but, although fulfilling the requirement of light weight, it could not on other grounds be justified. It appeared that nothing less than 80 ma. would furnish what was wanted. Such power necessarily implies weight, but various ingenious expedients were resorted to for reducing weight as much as possible. A special alternator was designed, raising the voltage and cycles as high as possible, and effecting a reduction in the iron and copper factors in the transformer. Weight was also reduced by cutting out the usual auto-transformer, and substituting tappings on the primary winding as a means of control. The new apparatus, as explained by Mr. H. T. Ferrier, the radiographer to the committee, is of the transformer type, specially wound to give, in conjunction with the alternator just mentioned, 100 ma. at 75,000 volt peak. It is therefore possible, at distances allowing of no distortion, to produce radiograms of the chest in one-twentieth of a second. By means of an apparatus known as a milliampere second relay, accurate and stabilized results are obtained. The car on which the unit is carried is rather a heavy type of vehicle; when stationary it becomes a miniature generating station, and with the apparatus withdrawn it is a dark-room, fitted with the usual appliances, with electrical resistances for keeping the temperature of solutions constant and the air content under control.

DRUG CONTROL IN INDIA

IN most, if not all, European countries the control of the sale of drugs is accepted as an obvious necessity. Most of our readers will probably be surprised to learn from the note by Dr. J. C. David, published at page 316, that no such control has hitherto been exercised in India, for anyone with sufficient capital to stock a shop has been permitted to sell drugs without reference to training or capacity. Moreover, there has been no system for checking the purity or quality of the drugs sold. It is satisfactory that this state of affairs is to be remedied, and that steps are being taken which will ensure a supply of reliable and unadulterated drugs. The dangers attending lack of control have been forcibly brought out in the evidence submitted to the committee that is now investigating this question in India. In a country where no system of control exists, it is not merely a matter of chance whether drugs of good or bad quality are received, since there is a definite tendency to dump in it any rubbish that is unsaleable elsewhere. Such reforms as Lieut.-Colonel Chopra and his committee may be able to institute will obviously be a great benefit to the public and to the medical profession. It is curious to note that the remedies of the indigenous systems of medicine may form a definite obstacle to the institution of reform. These remedies have remarkable virtues attributed to them—so subtle in most cases that the activity of the drug cannot be measured by any form of scientific test. In this country the old systems of folk-lore remedies have disappeared, but the advertisements of secret remedies still keep us familiar with the magic herbs whose virtues cannot be detected or measured by the methods of medical science.

NATIONAL COUNCIL FOR MENTAL HYGIENE

The National Council for Mental Hygiene, in its report for 1929–30, welcomes the opportunities for the early treatment of mental disorder which are now provided by the Mental Treatment Act, 1930. This Act reduces to a minimum the number of legal obstacles in the way of voluntary treatment, and of temporary treatment for those too ill in mind to seek of themselves the aid of psychological medicine. The council is earnestly desirous that full use should be made of these opportunities. Provision for voluntary treatment is optional under the Act, and the council regards it as its duty to see that such provision is really made by local authorities, and also that the provision for the treatment of non-volitional cases, which is compulsory, is of a suitable nature and likely to achieve its purpose. Although the Act is hailed as a striking advance in legislation, further concessions from Parliament, reflecting a public opinion still more enlightened, will

be necessary before the council can rest content that it has achieved its objective in this matter, and that the practice of psychological medicine has come into its own, relieved of its legal burdens and equal in the sight of the law with other branches of medical science. To this end the council recommends extension of temporary treatment as long as it is likely to benefit the patient, and extension also of the advantages of such treatment to early "unwilling" cases, which class under the Act is left to be dealt with under the principal Act. Attention is specially invited to the forthcoming second Mental Health Conference, which will be held from May 27th to 29th at the Central Hall, Westminster. As in other years, lack of money has been the great drawback to extension of the council's work. At a time of national economic depression it is difficult to obtain funds, but the council's appeal for them is felt to be justified by the need for maintaining a high standard of mental health and efficiency in order to meet the exacting demands of modern civilization.

"GINGER PARALYSIS"

We have previously noted (December 6th, 1930, p. 971) the extraordinary epidemic of paralysis, associated with many deaths, that occurred last year in Tennessee as a result of drinking adulterated ginger extract. The United States Public Health Service now announces that the causative agent has been identified as tri-ortho cresyl phosphate. This chemical was not introduced accidentally, but was added deliberately as an adulterant, probably in the form of technical tri-cresyl phosphate. Only a chemist of considerable ability would have thought of this substance as a cheap flavouring which would imitate the taste of ginger. This reckless experiment produced dire consequences, and the only circumstance that mitigates its guilt is that little or nothing was known about the toxic actions of moderate doses of tri-cresyl phosphate. Furthermore, it is interesting to note that extensive researches were needed to prove its toxic action, for the drug was completely harmless when given by mouth in large doses to monkeys, but produced typical paralysis when injected subcutaneously both in monkeys and in other animals. Apparently the drug is not absorbed from the alimentary canal of monkeys, and the erratic incidence observed in the occurrence of paralysis in those who drank the adulterated ginger extract suggests that there is a great individual difference in the extent of its absorption in human beings. This failure to obtain toxic symptoms in monkeys under conditions that produced them in men shows how difficult it is to prove by animal experiments that a chemical will be harmless when added to articles of human diet, and emphasizes the need for caution in introducing new chemicals into household use.

PARATYPHOID FEVER IN ESSEX

A communiqué issued by the Ministry of Health states that the total number of known cases of paratyphoid fever occurring in Essex between February 1st and 14th was 172, the districts mainly affected being Epping urban, Epping rural, Loughton urban, and the borough of Walthamstow. The infecting organism was *B. paratyphosus* B. The illness in many cases was severe, but the fatality has been relatively low, only four deaths having so far occurred. By arrangement with the London County Council, most of the patients have been treated in the Council's infectious diseases hospitals, but others have been admitted to the London Fever Hospital, the Connaught Hospital at Walthamstow, and the Ilford isolation hospital. Inquiries made by Dr. W. V. Shaw, a medical officer of the Ministry, in consultation with the medical officers of health of the county and of the districts concerned, indicate that the origin of the epidemic was the infection of a particular milk supply at a dairy farm in the Epping rural district. The infection seems to have been introduced by one of the employees on the farm, who, unknown to himself, was suffering from a mild attack of paratyphoid while at work and handling the milk before its distribution. For several days the milk thus infected was consumed by many people in surrounding districts, some of whom have suffered from the disease. At the farm in question all the employees have been examined and those suspected of possibly carrying infection, including the man considered to have been the source of infection, have been removed to hospital, and their places at the farm taken by other workers kept under close medical supervision. The distribution of milk from the farm was discontinued for the time necessary for the premises, milk utensils, etc., to be cleansed and disinfected to the satisfaction of the medical officer of health, and there is now no reason to apprehend further infection of the milk at this farm.

THE BANTING RESEARCH FOUNDATION

The Banting Research Foundation was brought into being in Canada in 1925, when a large sum of money was subscribed to encourage research in medicine and allied subjects throughout the Dominion on broad lines. A portion of the income from the fund is devoted to giving assistance to the investigations comprised under the heading of the Banting and Best Chair of Medical Research, while the remainder is available for individual workers in universities, university hospitals, and elsewhere. In the issue of the *Canadian Medical Association Journal* for January it is announced that the income of the Foundation is now in the neighbourhood of 30,000 dollars, and a list is given of the various recipients of grants, and of the lines of research which they are following.

The centenary meeting of the British Association for the Advancement of Science will be held in London from September 23rd to 30th next, under the presidency of General Smuts. The following Sectional presidents have been appointed: Section A (Mathematical and Physical Sciences), Sir J. J. Thomson; Section B (Chemistry), Sir Harold Hartley; Section C (Geology), Professor J. W. Gregory; Section D (Zoology), Professor E. B. Poulton; Section E (Geography), Sir Halford Mackinder; Section F (Economic Science and Statistics), Professor E. Cannan; Section G (Engineering), Sir J. Alfred Ewing; Section H (Anthropology), Professor A. R. Radcliffe-Brown; Section I (Physiology), Dr. H. H. Dale; Section J (Psychology), Dr. C. S. Myers; Section K (Botany), Professor T. G. Hill; Section L (Educational Science), Sir Charles Grant Robertson; Section M (Agriculture), Sir John Russell. A full preliminary programme will be issued in April. Forms of application for membership may be had from the secretary, British Association, Burlington House, W.1.

HEALTH OF THE ARMY

REPORT FOR THE YEAR 1929

The report[1] on the health of the Army maintains its reputation as a progressive medical annual, and medical officers are to be congratulated on having every year a concise review of the important medical statistics and scientific details connected with disease in the Army. The benefits would be enhanced if all members of the profession serving in the R.A.M.C were supplied with an official copy.

Although the admission rate has risen from 426.2 in 1928 to 468.5 per 1,000 of strength, the rise is insignificant, and is explained by the epidemic of influenza in the home commands during the early months of the year, which caused the ratio per 1,000 of strength for this disease to rise from 8.8 in 1928 to 36.8 in 1929. If the figures for the commoner diseases are examined, it will be seen that diseases of the digestive system, with a ratio of 100.0 per 1,000, diseases of the skin, 23.2, and diseases of the respiratory system, 20.4, show a slight increase over the figures for these diseases in 1928. On the other hand, local and general injuries (52.1), venereal diseases (35.0), and septic conditions (34.7), show a slight decrease. The totals, excluding influenza, show a very slight general rise to 265.4 per 1,000 in 1929, as compared with 261.0 in 1928. Of the ordinary infectious diseases, a slight increase occurs in the admission rate for diphtheria (1.5 per 1,000), enteric fever (1.5), and meningococcal infection (0.2), but the other infectious diseases met with at home and abroad either show a decreased ratio or are absent altogether. The increase in the admission rate for enteric fever is due to the increased incidence in India and Egypt, and is explained by the wider and more thorough employment of scientific methods of investigation, leading to closer co-operation between the ward and the laboratory, and the discovery of mild and abortive typhoid infections. This point is fully dealt with in the section of the report devoted to India. The decrease in the admission rate for malaria and dysentery in 1928 has not been maintained. Malaria shows a ratio per 1,000 of 41.2, as compared with 35.7 in 1928, and dysentery shows 6.5 against 5.8. The increase in both cases is comparatively slight, and may be considered as a normal variation in the yearly rate among troops occupying certain parts of the Empire.

There is a slight increase in the death rate from 2.36 per 1,000 of strength to 2.45, and also in the invaliding rate, 9.06 to 10.10. The principal causes of invaliding were again inflammation of the middle ear and tuberculosis, the former accounting for 260 cases compared with 246 in 1928, and the latter 233 against 207. These two diseases are a constant source of wastage to the Army and expense to the State. According to the report, investigations have been carried out in connexion with them, but it might repay both the Army and the State to continue these investigations and to insist on a more careful examination of all doubtful cases by skilled practitioners or specialists before enlistment.

Section II is interesting. It deals with the special departments of medicine, surgery, hygiene, pathology, dental treatment, and the medical examination of recruits. The reports indicate that there are many opportunities for medical research in the Army, and that a wider range of such work is being carried out, as, for example, on the association of cysticercosis as a possible cause of epilepsy, the investigations into pyrexia of uncertain origin, eye conditions, and the treatment of gonorrhoea. The average duration of treatment of each case of gonorrhoea is approximately three months, but an improvement has been effected by the Woolwich method, which has reduced the time to 48.9 days. The period is, however, still considerable when it is remembered that the soldier patient comes earlier under skilled treatment than the average civilian sufferer. The departmental reports show a tendency to become slightly ill-balanced, as, for example, in the hygiene section, where the inclusion of unnecessary minor details detracts from the general interest, and in the pathology section, which concludes with a list of publications, one entitled "Evacuation Time-Table for Motor Ambulances from A.D.S. to M.D.S."

Section III shows at a glance, by standard statistical tables, the incidence of disease in the different commands. An exception is the chapter on India, and rightly so, since India has always been a field of research among enthusiastic medical officers of both the I.M.S. and the R.A.M.C. There can be no doubt that the improved conditions under which both Europeans and Indians now live and work are intimately associated with the pioneer efforts of both Services. The subsection on India follows in miniature the general scheme of the report. The prevalence of dengue, sand-fly fever, pyrexia of uncertain origin, enteric fever, malaria, and dysentery is discussed at length, and interesting accounts are given of the investigations carried out during the year under review. This is encouraging in view of the fact that the opportunity for research work by many R.A.M.C. officers in that country has been somewhat neglected in late years. It is hoped that their efforts will be continued until the vexed question of pyrexias of uncertain origin and allied fevers is finally determined. A careful study of this part of the report will familiarize officers proceeding to India with the outstanding details of medical work in that country, and will encourage all to visualize the important medical work being done at the present time and the possibilities of research still to be carried out under the most favourable conditions.

It is interesting to note that increased attention is being given to dental treatment in the Army, and to record that close co-operation continues between the medical and dental officers in the treatment of diseases which may have relation to the condition of the teeth or mouth. As already pointed out, diseases of the digestive system are responsible for a high admission ratio in the Army. It is early yet to state what influence dental treatment may have on the incidence of this group of diseases, but it is hoped that this aspect of preventive medicine may be investigated and the results recorded. During the year, 61,109 soldiers, in addition to officers and families, received dental treatment, as compared with 61,738 in 1928.

Ireland

Prevention of Influenza

In view of the occurrence of influenza in various parts of the Irish Free State the Department of Local Government and Public Health has addressed a circular to local authorities which states that neither the incidence nor the mortality from this disease need cause anxiety at present. Having regard, however, to the possibility of a recurrence in an epidemic form, the Minister impresses upon sanitary authorities and their medical officers the necessity for taking immediate steps to deal with any threatened outbreak in their districts. The circular suggests that children from infected houses should be warned not to attend school, and that members of households where the disease is present should be advised not to attend cinemas or other crowded places. A number of other precautionary measures are outlined relating to the thorough ventilation of living rooms, the observance of strict cleanliness, and the regular use of a simple gargle. Directions are also given in regard to the nursing of patients, and the disinfection of rooms, clothes, and bedding, when the attack has passed.

Medical Officer of Health for County Dublin

At a recent meeting of the County Dublin Board of Health a scheme was submitted to the Department of Local Government and Public Health for the sanction of the Minister. The main proposals were

the appointment of a county medical officer of health, at a salary of £1,000, inclusive of travelling expenses, and the appointment of Dr. Cuffe, the present tuberculosis officer, to the position of assistant to the county medical officer of health. Other proposals included the appointment of two nurses, to discharge all duties assigned by the Board of Health, after consultation with the medical officer, and the appointment of all the present dispensary district medical officers of health, under the control of the county medical officer concerned, at the same remuneration as at present. The appointment of veterinary inspectors was referred to a subcommittee, to consult with the county council with a view to complete co-ordination of the veterinary services in the county.

Medical School Inspection in Northern Ireland

At a recent meeting of the Coleraine Regional Committee a report was read from medical practitioners of the neighbourhood in reply to a number of questions that had been submitted to them. The report stated that they were unanimously in favour of a dental scheme, but that such a scheme, to be effective, must make provision both for extractions and for fillings. They recommended that school children should be given a midday meal, which should be hot—at least in the winter season. This meal of bread and either milk or broth should be provided to necessitous children free of cost. Proposals were made for opening the schools at a later hour, as they considered that the children were not getting sufficient sleep. They agreed to issue medical certificates to children who were obliged to be absent from school on account of illness, at a flat rate of one shilling each. In cases for which operations for tonsils were recommended, and the parents were neither eligible for free treatment nor able to pay the ordinary fee for the operation, special terms might be arranged through the committee. Statistics in connexion with the medical inspection of children at transferred schools during the year indicated that of a total of 4,651 children on the rolls, 1,012 were found to be defective in health; this figure included 603 cases of defective teeth and 325 cases of nose and throat trouble.

Scotland

Records of Insured Hospital Patients

A meeting of the Scottish Branch of the British Hospitals Association was held in Glasgow on February 11th, at which Colonel J. A. Roxburgh presided. A discussion took place in regard to "Form M.R.," recently issued by the Department of Health to practitioners working under the national health insurance scheme, for use in correspondence with hospitals regarding patients whom they sent for treatment. An explanation of the form was given by Mr. N. F. M'Nicol of the Department of Health, who said that the hospital should be entitled to a note from the practitioner giving some details about the case, and stating why the patient was referred to hospital, while the panel practitioners should also be provided with information from the hospital staff regarding the treatment of the patient. An opportunity had arisen where the department thought it could be helpful, and at the instance of the insurance practitioners this form had been prepared and regulations had been framed which made it incumbent on every panel practitioner, when he sent a patient to hospital, to send with him a statement regarding his present condition. It was suggested that when the patient was discharged from hospital, or when a diagnosis had been made, a member of the medical staff concerned should state what had happened to the patient, and indicate the opinion of the consultant. There were two main general principles behind the form. The department thought it would increase the status of the practitioner if his record of his patients was complete. It also thought that the general practitioner might give a great deal of help in the scientific investigation of the causes of disease, and unless he had the full medical history of his patients this could not be done. A long discussion followed, during which special attention was directed to the great amount of extra clerical work which would be thrown upon the hospitals. It was pointed out by Colonel Thom of the Edinburgh Royal Infirmary that the number of insured patients treated at that hospital in the past year numbered 20,457; such a figure indicated that the adoption of the proposal would mean a large increase in clerical work. Mr. M'Nicol, in reply, admitted that the proposal would involve additional cost, but thought that the department would probably be able to find a sufficient sum from insurance funds to cover the cost of postages.

Glasgow Royal Infirmary

At the annual meeting of the Royal Infirmary of Glasgow Dr. J. Parlane Kinloch, medical officer to the Department of Health for Scotland, in moving the adoption of the report, referred to the erection of an auxiliary hospital to the institution at Canniesburn, Glasgow, whose construction is now being commenced. Funds amounting to £100,000 are available for the scheme. Dr. Kinloch said that this scheme introduced a group of modern ideas in hospital development in three important directions. In the first place, public opinion in regard to hospitals was tending towards a regional development. The teaching hospitals in the four university cities of Scotland would increasingly function as great casualty clearing stations and emergency hospitals, as well as for the treatment of acute remedial conditions. They would serve a whole ring of modern hospitals surrounding these cities, where fresh air, sunshine, and open-air treatment would be available to the fullest extent. In the second place, modern hospital construction on this side of the Atlantic favoured a horizontal type of building, one or two stories high, with a maximum provision of veranda accommodation, as contrasted with the typical American building of vertical design, many stories high. The plans of the Canniesburn Hospital would meet the requirements of Scottish hospital architecture, and would incorporate the whole range of new devices for facilitating administration, preventing infection, and securing the well-being of patients. Further, the directors proposed to provide paying wards, and they contemplated that these might be made available and be maintained under a mutual hospital insurance scheme. Dr. Kinloch predicted that this would be an unqualified success, and that participators in the scheme would receive benefits beyond measure for their premiums. Such a development was envisaged by the hospital clauses of the Local Government Act of 1929, which safeguarded the voluntary hospitals. With the development of a mutual hospital insurance service, they could see the beginning of a really adequate hospital service for Scotland, which would be available not for the poor alone, but for every citizen. He thought that the Canniesburn project merited enthusiastic support.

The report of the Royal Infirmary for the past year states that 127,215 persons received attention at the Infirmary—an increase of 7,251 over the figure for the previous year. The total ordinary revenue was £88,325, while the total ordinary expenditure was £110,924. Receipts, including endowments, amounted to £127,883, with total payments of £113,754, leaving a surplus of £14,129.

Crichton Royal Institution, Dumfries

The annual report of the Crichton Royal Institution for 1930, by Dr. C. C. Easterbrook, physician superintendent, states that there were 1,023 patients on the registers on January 1st, 1930, and the same number at the close of the year. During the year there were 319 admissions, 228 discharges, and 91 deaths; the total number of cases treated was 1,342, including 611 males and 731 females. The average daily number in residence was 1,020. Certified patients on January 1st amounted to 749, while the number of voluntary patients was 274. Voluntary patients under treatment during the year totalled 457; of these only 2 had to be certified. The report describes the year 1930 as "a red letter year for the rate-aided mental invalid." It points out that the Local Government (Scotland) Act of 1929, which transferred the functions of parish councils to the town councils and county councils, introduced much-desired reform in dissociating mental illness from pauperism, and by making the liability for the maintenance of the mental invalid during his treatment a charge on the county or town council rates, thus putting him on exactly the same footing in this respect as fever patients in hospitals for infectious disease and tuberculous patients in sanatoriums. The report also states that the new financial arrangements should promote earlier treatment by enabling the mental patient to go voluntarily to a mental hospital, instead of delaying until he is clearly certifiable as insane, as has been the usual practice in the past, largely because the patient could not obtain the benefit of the lunacy grant unless he became a pauper lunatic. Apart from humanitarian considerations early treatment under the voluntary procedure should prove in the long run an economy to the country by preventing much chronic and incurable mental invalidism. Attention is drawn to the fact that within recent years various parish councils in Scotland have begun to adopt the voluntary procedure, and the hope is expressed that the patients maintained by local authorities will come to mental institutions in future in the same proportion as private patients. The report points out that Scotland was in advance of England in its legislation for the mental invalid until the English Mental Treatment Act of 1930, but Dr. Easterbrook considers that if the Scottish county and town councils freely adopt the voluntary procedure for the admission of rate-aided patients, thus encouraging them to come sooner for treatment, many of the advantages gained for England by the Act of 1930 will be secured for Scotland under the Local Government Act of 1929. Of the 228 patients discharged during the year, 147 were voluntary and 81 certificated. The voluntary cases showed a recovery rate of 39.9 per cent., while 37.1 per cent. were improved.

The Certified Patient's Old Age Pension

In the course of his annual report for 1930, as medical superintendent of the Glengall Hospital, Ayr, Dr. Douglas McRae makes the following remarks on a legal anomaly affecting mental hospital administration: "Nearly a quarter of the admissions (24 per cent.) were over 65 years of age, but the prospect of a State pension seemed to have been an inducement for the relatives to keep the case at home, the patient, instead, becoming a charge on the local ratepayers. That the certified patient's old age pension is not available for his maintenance is a curious anomaly that has no parallel in the case of a person who has some means or has earned a pension for services rendered. In the case of a voluntary patient, however, his old age pension can be employed to meet the cost of treatment in a mental hospital. By such discrimination the 'stigma of certification' has thus received legislative approval! Formerly the stigma of certification had no practical significance except with the emigration authorities, who subject their applicants to a searching inquiry into their family history; and it has long proved a grievance to the criminal, who prefers a short term of imprisonment to a protracted sojourn in a mental hospital."

England and Wales

The Registrar-General's Statistical Review for 1929

The last of the three annual volumes constituting the Registrar-General's Statistical Review for 1929 has now been issued.[1] It contains the official analysis of the vital statistics contained in Parts I (Medical) and II (Civil) issued recently. Special sections are devoted to births, marriages, deaths, stillbirths, estimates of population, vital statistics of Great Britain and Ireland, and meteorology. The population of England and Wales at the middle of the year is estimated at 39,607,000 persons (18,969,000 males and 20,638,000 females). The total is in excess of the 1921 census figure by some 1,720,000 persons, an arithmetical increase of 0.56 per cent. per annum as compared with 0.49 per cent. per annum during the decade 1911–21. The marriage rate was 15.8, or 0.4 per 1,000 population higher than in 1928, and was the highest recorded since 1921, notwithstanding the prevailing economic depression. The birth rate was 16.3, or 0.4 per 1,000 less than in 1928, and was the lowest recorded in this country since the establishment of civil registration. The death rate was equal to 13.4, or 1.7 above that recorded in 1928, and was higher than in any year since the great influenza pandemic of 1918–19. The increase was greatest at the two extremes of life, and lowest among young adults. The first quarter of 1929 was marked by a period of severe weather—the coldest experienced since 1895—and a serious outbreak of influenza, which, with an increase in the deaths from cardiac and respiratory diseases, was chiefly responsible for the high death rate during the quarter. These adverse conditions were also responsible for the increase in the infantile death rate, which rose from 65 in 1928—the lowest hitherto recorded—to 74 per 1,000 live births. A new table (first published for 1928) shows the deaths and death rates from various causes during the first thirty minutes of life, and attention is drawn to the excessive mortality of illegitimate children at this age. The mortality from influenza was the highest experienced in any year since the great epidemic of 1918–19. The deaths ascribed to cancer during 1929 numbered 56,896, the highest number yet recorded for any one year. A table, continued from the previous year, shows the chief sites of cancer in order of frequency and the proportions of deaths for each site; and another shows the reduction in the mortality from diabetes, at ages under 55 years, since the introduction of insulin in 1923. At the later ages the mortality continues to increase, especially among females. Mortality from pernicious anaemia at various age groups from 1921 onwards shows the effects on death rates of the introduction of the new treatment with liver, the mortality being decidedly lower. A table and diagram comparing the consumption of alcohol with death rates from alcoholism and other allied causes from 1871 onwards exhibits the marked decrease of mortality both from alcoholism and from cirrhosis of the liver coincident with the decline in the consumption of alcohol.

Moorfields Dinner

The annual dinner of past and present students of the Royal London Ophthalmic Hospital was held at the Langham Hotel on February 12th. The chairman was Mr. A. H. H. Sinclair, ophthalmic surgeon to the Edinburgh Royal Infirmary. Among those present were Lieut.-General Sir H. B. Fawcus, D.G.A.M.S., Dr. T. Watts Eden (President of the Royal Society of Medicine), Professors Elliot Smith, Woollard, and Lovatt Evans, Sir Walter Fletcher, Sir William Lister, Sir John Parsons, Mr. Theodore Luling (chairman of the hospital), Mr. J. Herbert Fisher, Mr. Treacher Collins, and Mr. Holmes Spicer. The toast of "The Hospital and Medical School" was proposed by the chairman, and other toasts were proposed by Mr. R. Affleck Greeves and Mr. R. Foster Moore. The Dean, Mr. Charles Goulden, in presenting his report, spoke of the enlargement of the out-patients' department and other improvements that were soon to be put in hand by the board of management, whereby the clinical teaching could be carried out more conveniently. The school accommodation would also be extended, as well as the library and laboratories. The hospital itself had been enlarged during the past year, and there were now wards for private patients—a much-felt need. In the year under review the number of students working at the hospital was 160, of whom 98 were new: The number of lectures given amounted to 409, apart from the usual clinical teaching. In the public examinations many successes were recorded by students of Moorfields.

Royal Medical Benevolent Fund Guild

The women's branch of the Royal Medical Benevolent Fund, commonly known as the Royal Medical Benevolent Fund Guild, is a vital organization. This fact is easily understood when it is known that during the last two years thirty-seven new branches of the Guild have been opened. Yet, even so, there are many important towns without branches, and consequently many doctors' wives who have never heard of the activities of the Guild. We are asked to say that Mrs. Keppel Barrett, chairman of the Branch Organizing Committee, 102, Church Street, Kensington, London, will be most grateful for introductions to doctors' wives in provincial centres; for, if the work of the Guild increases every year, so also in a greater measure does the need of it. The medical profession has suffered with others from the hardness of post-war conditions, while it is common knowledge that the doctor is often the last person to have his bill settled. Further information about the Guild and its work can be obtained from the secretary, Royal Medical Benevolent Fund Guild, Tavistock House, Tavistock Square, London, W.C.

Society of Radiographers

The tenth annual dinner of the Society of Radiographers, held on February 13th, under the chairmanship of Mr. C. L. Winch, was a light-hearted affair; not often is the serious side of an art caricatured so ably as in the mock paper and discussion which was arranged on "The pitfalls of radiography." The guest of the evening, Professor G. Elliot Smith, acknowledged the debt which anatomists owed to radiographers in making possible the study of the living body. His own first contact with *x*-ray work was made in Egypt at the time the mummy of Thothmes IV was discovered. A dispute arose among the archaeologists as to whether this Pharaoh was a young man or a middle-aged man, and the mummy was too well preserved to permit of much anatomical investigation. To introduce an *x*-ray outfit into the museum was shocking to the susceptibilities of those concerned, but a cab was ordered to be at the museum after dark, and in this the ruler of the Egypt of three millenniums ago was transported through the streets of Cairo to a nursing home, where the only *x*-ray apparatus in the country at that time was installed. The outcome of that proceeding was a commission to examine all the royal mummies. Professor Elliot Smith added that a good deal of the information obtained from the fossils of early man recently discovered near Peking was got by means of *x* rays. The radiograms, of which he had received prints only that morning, helped greatly in interpreting the remains. They afforded information, for example, about the internal ear; if the exact position of the semicircular canals were determined, some idea might be gained as to the posture of the individual, and the way he carried his head. Major C. E. S. Phillips, president of the British Institute of Radiology, proposed the health of the Society of Radiographers, and to the toast of "The Visitors," proposed by Dr. Duncan White, there were responses by Dr. A. E. Barclay, Mr. W. E. Schall, and others. Mr. F. Melville, secretary of the society, mentioned that its membership was now 387, whereas ten months ago it was 295. He stated also that last year the society held examinations in Ceylon and at Alexandria.

Correspondence

OBSTETRICAL EDUCATION OF THE UNDERGRADUATE

SIR,—I have been much interested in the discussion about the training of undergraduates in obstetrics and gynaecology which has appeared in the *British Medical Journal*. As the Swedish medical curriculum has been mentioned there, I am perhaps permitted to say a few words concerning that question.

It is quite correct, as Dr. Letheby Tidy points out, that, theoretically, there is no reason why students in Sweden should not complete their medical studies in six and a half years. But, practically, it is almost impossible; in any case, I do not know that it really occurs. The average time for our medical curriculum is eight or nine years; in exceptional cases it has been seven or seven and a half years, due to overlapping in certain courses, especially in Stockholm. The reason for this very long curriculum depends mainly on two circumstances: first, that all our clinical training is compulsory *before* the examination, not *after* it; and secondly, on our system of examination. As Dr. Tidy rightly says, there is no pressure on students to present themselves at a fixed time, and so the time slips easily away. The result is, as I mentioned before, an average curriculum of eight or nine years, as Professor Munro Kerr has stated in his paper.

Concerning the main question about the training in obstetrics and gynaecology, the time in Sweden is four months, and now I am informed that the corresponding training in Glasgow is carried out in three months. There is no doubt but that a satisfactory training can be given in three months too, supposing a sufficient number of confinements or a limited number of students. In Sweden we are satisfied with four months, but there are people here, too, who consider three months quite sufficient. To me, with my experience of thirty years' clinical teaching in this subject, it is difficult to understand how to keep the undergraduates busy for six months with only obstetrics and gynaecology without wasting their time. Certainly I agree fully with Professor Munro Kerr on that point.

There is one other difference between our teaching and the Scottish one which may perhaps be worth mentioning. In our training we insist that the students, before finishing

their four months, shall have personally applied forceps upon a patient. As I understand, this opportunity is not given to the students in Glasgow. There are reasons for both. To us it seems safer that the first forceps should be applied under the direct control of the professor or his first assistant, but Professor Kerr is of course right when insisting that a thorough training in obstetrical operations is possible only by gaining personal experience and profiting by mistakes. Experience in obstetrical operations and complicated obstetrical cases can only be gained by a special training after graduation. Just as it is necessary that the surgeon should receive such training before he practises as a surgeon, so it is necessary that those who are going to undertake obstetric operations should receive a similar training.

In Sweden, the obstetric practice in more populous areas is now mainly carried out in such a way that complicated cases are sent to the obstetrical hospitals, of which we now have a great many, very well equipped. In the country, the general practitioner assists the midwives in complicated cases by applying forceps or performing version; but if it comes to very serious cases—for instance, a rupture of the uterus or a narrow pelvis—those cases, too, are sent to the nearest hospital. Outdoor practice, such as is arranged in certain countries, by the staff of the hospitals who go out to assist midwives in the patient's home, is not very much in use in Sweden.

There are many more points of interest to discuss, but I must limit myself to what I have said. With thanks for your courtesy, I am, etc.,

Lund, Sweden, Feb. 9th. ELIS ESSEN-MÖLLER.

X-RAY THERAPY IN MALIGNANT DISEASE OF THE LUNG

SIR,—It was with the greatest interest and pleasure that I read Dr. Ffrangcon Roberts's admirable letter on this subject in the *Journal* (p. 283). Those of us who have had opportunities of dealing with large numbers of cases of primary malignant disease within the thorax know only too well the limits and disappointments of treatment in this distressing condition; wherefore it is all the more important that we should strive for more co-operation in the spirit of generous understanding for which Dr. Roberts pleads. In response to his restrained and courteous letter I should like once again to express the conviction, which I have had occasion to record elsewhere, as to the undoubted benefit of *x*-ray treatment in primary lung carcinoma.

No one of experience can be optimistic enough to suppose that the results are, at present, anything more than palliative, but surely in a condition such as this it behoves us to omit no detail which may serve to postpone or to diminish the grosser forms of suffering which characterize the later stages of this particular form of malignant disease. That we do thus benefit these patients, and that we do sometimes succeed in prolonging life under conditions more tolerable than would obtain without radiation, is a conclusion which, in company with my radiological colleagues at the Brompton Hospital, I have reached after seeing a very considerable number of cases. I am fully aware that it is extremely difficult in the absence of any definite scientific control accurately to appraise the results of any given therapeutic measure (of this we have ample evidence in the ceaseless appearance of tuberculosis "cures," for example), but I cannot believe that the clinical impressions of those who have carefully watched the progress of many patients ought lightly to be set aside as without significance.

For some years I have endeavoured to urge upon post-graduate students who are taking up the study of diseases of the chest the importance of spending as much time as they can possibly spare in the *x*-ray department, in order to learn the real meaning of co-operation between clinician and radiologist, an ideal which is talked of sententiously by so many clinicians and pursued by so few. It means, of course, no little extra demand upon the time and patience of the clinician; but for the attainment of results in medicine, as in everything else in this world, there is, in my humble opinion, no substitute for the taking of trouble or for the exercise of personal energy.—I am, etc.,

London, W.1, Feb. 14th. MAURICE DAVIDSON.

SIR,—In the *Journal* of February 14th Dr. Ff. Roberts takes Mr. Tudor Edwards to task for his statement that he has yet to see a patient suffering from malignant disease of the lung benefited by *x*-ray therapy. Dr. Roberts is in the fortunate position of having had cases in which there has been "undoubted material benefit as regards alleviation of symptoms and prolongation of life," yet no exact details are supplied as to the number of cases in which this partial success is claimed, and one cannot conclude from his letter that Dr. Roberts's results differ appreciably from those of other radiologists. It must be remembered that intrathoracic surgery is as yet in its infancy, and that there is good reason to hope that the results obtained will show a great improvement in the next few years, whereas *x*-ray therapy is a well-established method of treatment which has had ample opportunity of demonstrating its possibilities in the treatment of intrathoracic malignant disease.

In a paper recently published (*Quart. Journ. Med.*, October, 1930), Nicholson and I reviewed the results of treatment in a series of 16 cases, each treated by more than ten applications of *x* rays. The average duration of life from the onset of the first symptom was 14 months in these cases, compared with an average of 10.9 months in our whole series of 100 cases, and these figures may be compared with those of Kidd, who, in 1883, found the average duration of symptoms to be 13.2 months in a series of similar cases.

From an unbiased point of view the results of *x*-ray treatment in intrathoracic malignant disease may be summarized as follows:

1. In sarcoma, a rare condition and usually mediastinal in origin, there is frequently dramatic improvement for a considerable time, although the prospect of ultimate cure is remote.

2. In bronchial carcinoma, the most common tumour, there are three main groups of cases. In the first and smallest group there is marked clinical improvement, which may last up to three years or even longer, but which, so far as I am aware, is never so complete as to be entitled to the term "cure." The second group comprises the great majority of the cases, in which there is no striking change, or perhaps a temporary alleviation of symptoms, the duration of life being extended by a few weeks or months. The third group, which fortunately is small, consists of cases which are made worse by *x*-ray treatment, either as a result of pronounced local reactions, or of rapid dissemination of the growth to other parts of the body.

As I have previously pointed out, the efforts of both surgeon and radiologist are hampered by the fact that metastases are usually present in inaccessible situations before the patient comes under their care. The essential need to-day is early diagnosis, which, if it could be combined with some reliable general treatment, chemotherapeutic or otherwise, might conceivably revolutionize the prognosis in this, at present, one of the most hopeless varieties of malignant disease.—I am, etc.,

London, W.1, Feb. 15th. JAMES MAXWELL.

THE INCISION FOR APPENDICECTOMY

SIR,—I read with much interest Mr. Southam's article on the incision for appendicectomy in your last issue. I am quite in agreement with him that the right rectus incision is the best for general exploration, but that in cases of acute appendicitis the incision is some distance from infection. Surely this objection is also valid, although to a lesser degree, if Battle's incision is used.

Mr. Southam refers to drainage through "McBurney's" (actually Elliot's) incision, and complains that inguinal hernia may then develop owing to implication of the ilio-inguinal nerve in scar tissue. In the *British Journal of Surgery* (vol. x, No. 40, 1923) I published a paper based on 1,503 cases of acute appendicitis, reviewing the complications following drainage through various incisions. The results showed a much greater incidence of complications following drainage through the gridiron incision than through any other incision. Drainage may be necessary for pelvic or general infection, or for localized infection in the right iliac fossa. In the former case suprapubic drainage is obviously indicated, and in the case of infection of the right iliac fossa a stab wound in the flank is as direct and dependent as possible, and if made obliquely is parallel to the ilio-inguinal nerve. The original wound may then be partly closed, preferably in the manner suggested by Professor Wilkie in your last issue, and the risk of infection and subsequent scar tissue is reduced to a minimum, with consequently little risk of implication of the ilio-inguinal nerve. Furthermore, incisional herniae are seen much more commonly after an infected lower right rectus or Battle's incision than in connexion with a gridiron incision.—I am, etc.,

R. J. MCNEILL LOVE,
London, W.1, Feb. 15th. Surgeon, Royal Northern Hospital.

MORTALITY OF ACUTE APPENDICITIS

SIR,—Professor Wilkie's thoughtful paper (*Journal*, February 14th, p. 253) calls for some criticism, which I know very well he will welcome. He believes that the mortality rate of acute appendicitis has not diminished in the past twenty years, despite the manifold improvements in all matters relating to the treatment of the disease during the same period, and ascribes our failure to reduce the mortality to the want of recognition of the most lethal type (the acute obstructive variety) at a sufficiently early period to permit of operation in the pre-perforation stage, though he observes, as all other surgeons do, that the majority of cases of acute appendicitis do come to the surgeon now much earlier than formerly. While I agree that acute obstruction of the appendix is not yet sufficiently regarded as a distinct type of appendicitis, I doubt very much if in practice the diagnosis of acute appendicitis is delayed on that account. It is generally realized in the profession now that every case of acute appendicitis holds out the possibilities of the gravest peril, and that the only safeguard against these is early diagnosis and operation; the absence of rise in pulse rate, and particularly of the temperature, in the first twelve, or even twenty-four, hours is of little account in arriving at a diagnosis in this period. With the general public the position is very different; the use of the clinical thermometer by parents and school authorities, and the false security engendered by a normal reading, is, in my experience, more responsible for delay in calling in medical advice in this and other acute abdominal diseases than any other factor. If there is one type of appendicitis that is yet apt to be overlooked in its early stages by the profession it is that in which the appendix is pelvic in position, and this, irrespective of the pathological type, remains a trap even for the most experienced practitioner.

Is Professor Wilkie correct in stating that the death rate of acute appendicitis is as high to-day as it was twenty years ago? I venture to assert that he is not. It is true that the Registrar-General's returns show approximately the same number of deaths from appendicitis per million of the population now as those of twenty years ago, but these figures give us no idea of the incidence of the disease during the same period. If we examine the statistics of any large general hospital we shall find, I believe, that the number of acute appendicitis patients has substantially increased during the period in question, while the percentage of deaths has diminished. For example, at the Manchester Royal Infirmary in three years ending 1915, 1,650 cases of acute appendicitis were treated, with a death rate of 12.5 per cent.; in the three years ending 1926, 2,490 cases were treated at the same hospital, with a mortality rate of 6 per cent. It should be pointed out that, during the period quoted, there had been a material increase in the hospital accommodation of the surrounding area, but not in the surgical beds of the hospital concerned. It is fair to assume, therefore, that the actual increase in the number of cases in the district was greater than is shown by these figures. I suggest that the striking decline in the mortality rate shown by the foregoing statistics is in accord with the personal experience of every surgeon who has practised during these years, and therefore may be regarded as representative of a general decline in the case mortality, creditable to the teacher and practitioner alike.—I am, etc.,

Manchester, Feb. 16th. H. H. RAYNER.

SIR,—Professor Wilkie's timely and thought-provoking article on acute appendicular obstruction must earn the gratitude of all medical practitioners.

There can be very few of us who have not at one time or another had the misfortune to observe cases such as he describes without fully appreciating the disastrous result of observation and consequent delay until the diagnosis has suddenly become all too clear, with the rapid onset of general peritonitis, and almost necessarily fatal termination in spite of operative intervention. It is a trap into which many of us have fallen, and I have seen physicians of great experience commit the same error of judgement.

It is perfectly true that ignorance of the fundamental pathology of the condition is largely responsible for this state of affairs, but to my mind a very important reason for the fatal delay is the association of equivocal symptoms and signs with a normal temperature and pulse rate. We have all been taught to look for signs of constitutional disturbance produced by inflammation—for example, an increase of temperature and of pulse rate—and while these have remained normal we have been content to watch and wait, without realizing that to do so is to sit on a volcano!

A cogent reason for the ignorance of students and young practitioners of this condition is its comparative rarity in hospital practice, because it is only after the obstructed appendix has burst, and the classical signs of general peritonitis have supervened, that these cases are sent into hospital. It is the duty of those of our surgeons who are post-graduate teachers to emphasize this most important point, and when the lesson is well learnt, but not until then, is it likely that acute appendicular obstruction will become a familiar and well-recognized condition, with consequent heavy reduction in the mortality therefrom.—I am, etc.,

Dagenham, Feb. 16th. LOUIS F. BECCLE, M.B., B.S.

THE ENIGMA OF THE CHILBLAIN

SIR,—Some years ago I went to give a lecture at a big school in the Midlands, and the head master told me that the system of heating the school rooms by hot-water pipes had completely broken down, but he had carried on, keeping the boys warm enough by extra clothes and exercise. A notable result had been the disappearance of all chilblains, which in previous years had been very common. It is not, then, exposure to cold, but artificial warming of cold extremities, which works the mischief. Artificial light baths are, I find, a most excellent method of treatment.—I am, etc.,

Chalfont St. Peter, Feb. 15th. LEONARD HILL.

SIR,—Dr. Izod Bennett dismisses the enigma of the chilblain with a rather contemptuous gesture, but I can assure him that the question is by no means as simple as he would seem to have us believe. When I saw his name at the foot of the letter in your last issue I hoped we were to be told that the real cause of chilblain was to be sought in the digestive apparatus, to the study and lucid exposition of which he has given so much time and service, and I was disappointed to find that he takes a very different view.

I have for many years been convinced that in some cases at any rate the tendency to chilblain is a metabolic matter. I have suffered from that tendency all my life, and still do so, and I have always found that indiscretions in diet, or worry and anxiety (they always give me dyspepsia), are far more important factors than any other. One of the many curious things about a chilblain is the rapidity with which it will disappear when the metabolic cause is removed. A cholagogue or a day's fast will cure in a few hours a hot, angry, painful swelling, large enough to prevent the wearing of the ordinary boot. I may add that neither calcium internally, nor anything externally, has ever afforded me any relief; also, that I appear to be an exception to Dr. Izod Bennett's rule, inasmuch as being abroad has never protected me against a chilblain on the not infrequent occasions when I have otherwise deserved it.—I am, etc.,

St. James's, S.W.1, Feb. 16th. LEONARD WILLIAMS.

TREATMENT OF VARICOSE ULCERATION

SIR,—Sir Leonard Hill's letter (February 7th, p. 240) on the question of stagnation of tissue fluids in the lower limb is most opportune. Relatively few medical men seem to adopt the at least thirty years old method of applying Unna's paste casings while the patient, including his head, is lying horizontal, and after the affected limb has been raised to an angle of forty-five degrees for twenty minutes. The casing makes an additional skin, which, though inextensible, does not strangulate the foot when the patient resumes the erect attitude. The foot should be included in the casing. This method, in my experience, is better than straining the bandages on in the way described by Dr. Twiston Davies, which is difficult to do evenly, and is apt to produce ridges in the oedematous skin. Either the ready-made impregnated bandages may be used or the paste may be applied with a paint-brush over open-wove bandages, the latter being the better in my experience, and the combination—namely, a thick coat of the paste over three layers of the impregnated bandages—being better still. The greater the degree of oedema the stronger should the casing be.

McPheeters's observations with the fluoroscope (*Surgery, Gynecology and Obstetrics*, July, 1929) are an interesting confirmation of the absolute need for an appreciation of the hydrostatics and hydrodynamics of the problem by all those practising the injection treatment. How many have not observed the swelling of the ankles which occurs for a few weeks after treatment, while the circulation is increasing in the deep veins? In many cases varicose veins begin to cause symptoms and increase when the patient stops pedal-cycling. The saddle carries the weight and reduces the height of the columns of blood. The muscular action pumps the blood through the veins more easily under these conditions and perhaps more actively or tonically than in walking. Certain it is that a return to cycling quickly reduces the oedema, and if a bicycle or tricycle is not to be had the use of a treadle sewing machine three times a day with the fly-wheel braked is excellent.—I am, etc.,

Aberdeen, Feb. 9th. G. H. COLT.

SIR,—There is no doubt that Dr. Adamson is right in his contention that the principle of firm bandaging in varicose ulceration is extremely old. But the system of treatment of varicose ulcers by means of elastoplast, as developed by Mr. Dickson Wright, is not only based on this highly important principle, but also takes advantage of the benefit always afforded to indolent ulcers when they are protected by an occlusive dressing which is only removed at infrequent intervals. This method of treating varicose ulcers is also hallowed by antiquity, for it appears first to have been devised and employed by Thomas Baynton of Bristol about the year 1790. He was the first to treat ulcers by means of a plaster dressing changed only about once a week. He, too, was very successful, although the only plaster at his disposal was home-made lead plaster; but the method fell into desuetude, probably on account of the frequency with which it caused dermatitis. The introduction of modern zinc oxide plaster on a rubber base has made his method far more practicable and diminished the risk of dermatitis, and I myself, who have been interested in varicose ulcers for many years, have often induced them to heal by strapping them with strips of this plaster, changing it only once, or at most twice, a week. But I am sorry to say that in many instances I have failed, because either the patient would not tolerate it or it caused irritation, and in ulcers extending more than two inches round the circumference of the leg it has always been useless. It seems to give the best results in long but somewhat narrow lesions.

The elastoplast bandage combines the application of both these principles—(1) firm pressure, (2) occlusive plaster dressing. Hence I think it is justifiable to consider it a new method of treatment, and certainly the results obtained from its use are far superior to anything previously seen in the treatment of varicose ulcers. Dr. Adamson states that equally good results can be obtained with the simple flannel bandage properly applied, and that it is even more scientific because "by the daily reapplication of the bandage the pressure is repeatedly adjusted to the gradual shrinkage of the swollen leg." Possibly that is true, but who is to reapply the bandage daily? If the patient (or her friends) attempts this scientific operation it is quite certain that the results will be deplorable, and, on the other hand, the daily attendance of the medical practitioner for the purpose, either at the patient's home or in the surgery or out-patient department, is almost always impossible. Now the elastoplast bandage needs only to be applied once weekly, and, owing to the fact that it is made from an elastic fabric, it *does* adjust itself to the gradual shrinkage of the swollen leg, and the diminution in the size and weight of the affected limb is one of the most striking benefits of its application. Another striking fact is that under the elastoplast

bandage the ulcers clean themselves, and quickly lose the offensive odour so often associated with " bad legs."

In my opinion it is not too much to say that the introduction of the elastoplast bandage has revolutionized the treatment of varicose ulcer; it has even been of more benefit than the injection treatment of the varicose veins themselves. The only objection to it is that occasionally it sets up so much cutaneous irritation that generalized dermatitis results; but, luckily, such cases are not frequent, much less frequent than with ordinary zinc oxide plaster.—I am, etc.,

London, W.1, Feb. 15th. H. HALDIN-DAVIS.

SIR,—At the present time the methods of treating all forms of gravitational ulcer resolve themselves into three main groups: (1) those directed at the removal of the effects of gravity when vascular equilibrium does not prevail in the lower part of the leg when in the standing position; (2) local treatment of the ulcer alone; (3) treatment designed to correct a supposed error of calcium metabolism. The first is logical, the second unreasonable, and the third ridiculous.

There are perhaps twenty different ways of applying the first method, of which Wiseman's and Unna's are probably the most used; of the second method there are at least two hundred different variations. The time-hallowed custom of dressing the ulcer dies hard, so that the first method is seldom used alone, some effort generally being made to treat the ulcer with medicaments, the treatment thereby losing greatly in efficacy, as a rule.

Space does not allow me to contrast fully the method originated at St. Mary's Hospital with other supportive measures except in one important respect. I have at the present moment 190 gravitational ulcers under my personal care at St. Mary's Hospital, involving me in two hours' work each week. If I discarded my present routine for that recommended by Dr. Adamson I would be faced with the " daily reapplication " of 190 " flannel bandages." *Res ipsa loquitur.*

The tendency to make this subject controversial is of the greatest value; Dr. Adamson's letters, and the replies they evoke, all emphasize *the* vital point in the treatment, and, moreover, attract attention to what is surely one of the most neglected diseases afflicting mankind.—I am, etc.,

London, W.1, Feb. 13th. A. DICKSON WRIGHT.

SIR,—I am afraid that our paper on this subject must have been very obscure, because I see that further misunderstandings have arisen.

I admit I should have said " 99.37 per cent. successful results," instead of " 100 per cent.," for it will be remembered that out of a total area of 970 sq. cm. of ulcer treated there remained 5 sq. cm. unhealed in one patient. Many of the patients referred to by Dr. Adamson as being still under treatment had had their ulcers healed weeks before, but were still having support for their legs to guard against relapse of the swelling.

The best way to discredit this method of treatment is to say that it is identical with the many bandaging systems which have been devised, and which are now relegated to the dust-heap. As far as I know, Dr. Adamson has never seen our method carried out. I still hope that, in spite of his authoritative criticism, practitioners with these cases on their hands will attempt the Dickson Wright method of treatment.—I am, etc.,

Hove, Feb. 14th. J. H. TWISTON DAVIES.

ETHYL CHLORIDE BY THE CLOSED METHOD

SIR,—At an inquest held on February 6th on the death of a child at the Birmingham School (Tonsil) Clinic, I gave some figures of administrations of ethyl chloride by the closed method. As reported in the *Birmingham Post* these might be taken as referring to anaesthetics in general.

In 1919 I reported in the *British Medical Journal* a series of 40,000 cases in Birmingham without a death, 11,000 of these being my own. Since then I have given ethyl chloride by the same method in over 20,000 cases, most of them at the school clinic, where, in seventeen years, 23,000 operations for the removal of tonsils and adenoids have been performed without a death until the present case. This was a girl of 9, well nourished and apparently healthy. She had been taken to bed after the operation, had recovered reflexes, and taken notice when spoken to, but collapsed suddenly and died immediately. The post-mortem examination made by Professor Haswell Wilson showed a very large thymus and great excess of lymphoid tissue throughout the body.

In view of my earlier communications I feel it right to report this, the only death in my own experience associated with the administration of ethyl chloride by this method.—I am, etc.,

Birmingham, Feb. 9th. C. B. DALE.

AVERTIN ANAESTHESIA

SIR,—The report of my remarks in the discussion at the Medical Society of London (February 14th, p. 265) represents me as saying that " avertin is always given by the mouth." I shall be glad if you will allow me to draw attention to this printer's error, and substitute the word " rectum " for " mouth." As far as I know, avertin is never given by the mouth.—I am, etc.,

London, N.W.1, Feb. 16th. FRANCIS E. SHIPWAY.

*** We much regret the slip.—ED., *B.M.J.*

FUTURE OF THE R.A.M.C.

SIR,—I have just been reading the report of the Proceedings of Council of the British Medical Association with reference to the shortage of officers in the Naval and Military Medical Services. As an officer who has had a long period of service in the R.A.M.C., and who after retirement had ten years' experience of work in a county public health department, I should like to make some comments.

When the present rates of pay and retired pay for the R.A.M.C. were granted the cost of living was about 120 per cent. above pre-war cost. The new rates of pay were a great improvement on the pre-war rates, though the increase was not nearly in proportion to the rise in the cost of living. As regards retired pay, the disproportion was much greater; the increase varied considerably, at some periods of service the new scale of pension being very little more, or even less, than the pre-war rate, and at the best the increase was not more than 25 per cent. above the pre-war scale. This increase has been subject to progressive diminution as the cost of living has fallen. As regards rates of retired pay, medical officers were originally granted an increase far less than the cost-of-living increase, and this very inadequate sum has been considerably whittled down as the cost of living has fallen.

In the Public Health Service salaries are now double to three times what they were before the war, in most cases a superannuation allowance is assured, the salaries are fixed and not subject to a reduction every three years, and the superannuation allowance bears a definite relationship to the salary attained before retiring.

The block of promotion which makes the prospects of many of the R.A.M.C. majors hopeless is something which was not anticipated, and it is sheer bad luck, and not lack of ability, in the majority of cases, which leads to their retirement.

In comparing the prospects of officers in the Naval and Military Medical Services with those of members of the Public Health Service and of the Colonial Medical Services one must remember that, in the R.A.M.C., majors who have been superseded for promotion are retired at twenty-five years' service (age about 50), majors not superseded for promotion and lieutenant-colonels at the age of 55, while members of the Public Health Service can go on till they are 65, if they come under a superannuation scheme, and until no longer fit for duty if they do not. I believe medical officers in the Colonial Services are not retired at so early an age as 55. This is a matter of great importance to young men weighing up the advantages and disadvantages of the respective careers. In the R.A.M.C. there is the by no means improbable prospect of being retired compulsorily at the age of 50, on a pension totally inadequate in the case of a man with a family, and at a stage when the expenses of educating a family are probably at the maximum. At the age of 50 it is no easy matter to start a fresh career.

I shall not say anything about the disadvantages of foreign service, which nowadays means in most cases service in India under conditions by no means as pleasant as in the days gone by. The greater the scarcity of regular officers, the less the amount of home service, and the more frequent and expensive the changes of station. Not only are there very few entrants secured for the R.A.M.C., but a large proportion of those secured resign their commissions in a year or two. There are also many voluntary retirements among more senior officers. Unless something is done, and done soon, to put matters on a better footing, the R.A.M.C. will cease to exist, or will at least be a very different service from the R.A.M.C. of the years before the war. It will be a matter of regret if the British Medical Association, which did so much to assist the R.A.M.C. to attain the standard of efficiency and reach the prestige it then held, is unable to prevent the work of so many years from being undone.—I am, etc.,

J. G. McNAUGHT,
Penzance, Feb. 10th. Lieut.-Colonel R.A.M.C. (ret.)

THE LONDON CLINIC AND NURSING HOME

SIR,—I read with great interest the letter in your issue of February 14th, in which the objects and ideals of the above institution, and "some details of the means by which it is hoped they may be achieved," are set out. Having felt for some time that the best method of attaining the objects in question was the provision of graded accommodation for paying patients in the large voluntary hospitals of London, I am keenly interested in this alternative proposal. I believe that many besides myself would be grateful if the information in the letter referred to were supplemented by answers to the following questions:

1. Will general practitioners be able to admit patients under their own care to rooms in the nursing home section of the London Clinic?
2. What is the proposed minimum charge for a single room, and what services will this cover?
3. What laboratory facilities will be provided in the clinic?
4. Will any consultant be able to admit his patients?
5. What special privileges, if any, will those consultants with consulting rooms on the spot enjoy as regards the nursing home section of the clinic?

—I am, etc.,

London, W.1, Feb. 16th. ERIC PEARCE GOULD.

Obituary

The death occurred, on February 12th, after a long illness in a nursing home in Edinburgh, of Mr. RICHARD MUIR, demonstrator of pathological and bacteriological methods in Edinburgh University. Mr. Muir was well known to many generations of students, and took part in the preparation and illustration of countless pieces of pathological research. Over fifty years ago he was appointed first laboratory boy by Dr. D. J. Hamilton, who was then assistant to Professor Sanders, and engaged in starting the first practical classes in pathology held in Great Britain. Mr. Muir's skill in pathological and bacteriological technique, and in draughtsmanship, added greatly to the efficiency of pathological teaching and to the success of pathological research in the Edinburgh medical school. Ultimately his exceptional ability in this direction was recognized by the University Court, which appointed him a university demonstrator. Outside his laboratory work he took a keen interest in archaeology, art, and music. By helping to found some years ago an association for pathological and bacteriological laboratory assistants he did much to raise both the status and efficiency of these workers.

The following well-known foreign medical men have recently died: Professor CONSTANTIN VON MONAKOW, formerly director of the Nerve Policlinic and Institute of Cerebral Anatomy at Zurich University, founder and editor of the *Schweizer Archiv für Psychiatrie und Neurologie*, joint founder of the Society of German Neurologists and founder of the Swiss Neurological Society, aged 77; Professor EMILE GLEY, professor of general biology at the Collège de France, and formerly president of the Académie de Médecine, aged 73; Dr. PAUL BUSQUET, librarian of the Académie de Médecine and author of several works on the history of medicine; Dr. P. UBALDO FERNANDEZ, professor of puericulture at Buenos Ayres; Dr. ANDRÉ LÉRI, an eminent Paris physician; Professor F. CRONER, a Berlin chemist and bacteriologist; and Dr. EDUARD PIETRZIKOWSKI, extraordinary professor of surgery at the German University of Prague.

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel Samuel Ferguson Bigger, who died at his residence in Bray, co. Wicklow, on February 2nd, was born in Belfast in 1854. He received his medical education in Liverpool, and became a member of the Royal College of Surgeons of England in 1875. Subsequently, during one of his periods of leave, he obtained the M.B. of London University. In 1877 he passed the entrance examination for the Indian Medical Service, obtaining a high place, and was gazetted surgeon in 1878 and attached to the 3rd Punjab Cavalry. His service in India, which was chiefly on the military side, included the Afghan war of 1879–80, in which he took part in the Zaimusht expedition, the operations in the Kuram Valley, and the capture of Zawa (medal). For his work with the Chin-Lushai Expeditionary Force in 1889–90 he was mentioned in dispatches, and received the medal and clasp. He was principal medical officer of the Third Brigade with the Waziristan expedition of 1894 (clasp), and took part in the action of Dargai in the Tirah campaign (mentioned in dispatches, medal with two clasps). While in India he established a considerable reputation as an operating surgeon, particularly in operations for stone and cataract. He was promoted lieutenant-colonel in 1898, and retired from the service in 1903. Since his retirement he had lived at Bray, where he was well known as a chess player and gardener and, in many parts of Ireland (as previously in

India), as a skilled fisherman. He is survived by his widow and two brothers—Colonel F. C. Bigger, I.S.O., and Sir Edward Coey Bigger, M.D.

Lieut.-Colonel Henry Thomson, Madras Medical Service (ret.), died in Edinburgh on December 16th, 1930, aged 73. He was born in Aberdeen on February 1st, 1857, the son of James Thomson of Aberdeen, and was educated in the University in that city, where he graduated as M.B. and C.M. in 1879, and as M.D. in 1908. Entering the Indian Medical Service as surgeon on September 29th, 1883, he became lieutenant-colonel after twenty years' service, was placed on the selected list on October 29th, 1910, and retired on February 1st, 1912. His first ten years' service were spent on military duty. In April, 1891, he entered civil employ as a district surgeon in the Madras Presidency, in 1898 was appointed Durbar physician to the native State of Travancore, and in April, 1906, sanitary commissioner of Madras, holding that post till his retirement. He served in the Burma campaign in 1886-87, taking part in the operations of the 4th and 6th Brigades, and receiving the frontier medal with two clasps. In 1915 he rejoined for service in the war of 1914-18, returned to India, and was reappointed to his former post of sanitary commissioner, Madras, which he held up to 1919.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on February 14th the following medical degrees were conferred:

D.M.—C. P. Blacker.

B.M.—J. H. Chitty, W. E. S. Merrett, F. Bell.

UNIVERSITY OF CAMBRIDGE

Cessation of Diplomas in Public Health, Hygiene, and Tropical Medicine and Hygiene

The Registrary announces that the University has decided to discontinue the award of Diplomas in Public Health, Hygiene, and Tropical Medicine and Hygiene when the present courses end, and that no further candidates for these diplomas will be accepted.

This notice does not apply to the Diploma in Medical Radiology and Electrology.

UNIVERSITY OF LONDON

At its meeting on February 11th the University Court had before it a letter from the London County Council stating that the Council's block maintenance grant to the University in each of the four academic years 1931-32 to 1934-35 would be £125,000. This figure represents an increase of £20,000 on the Council's grants for the current year, and of £44,000 on the grant to the University and its Colleges in the year 1929-30. An expression of the Court's high appreciation of the support thus accorded to the work of the University has been conveyed to the County Council.

The regulations for the M.B., B.S. examination have been amended by the substitution of the following for the last paragraph under Group II (Red Book, 1930-31, p. 211; Blue Book, September, 1930, p. 263):

> The examination in Obstetrics and Gynaecology will consist of (*a*) a paper of three hours' duration, (*b*) a clinical examination, (*c*) an oral examination, including questions on specimens and appliances.

The date on which the change will become operative will be announced later.

The regulations for the Diploma in Psychological Medicine for the year 1931-32 and subsequently have been amended by the omission from Regulation 4 for the diploma of the words in italics:

> . . . A candidate who enters for both Parts A and B on the same occasion (March-April or October-November), but fails to satisfy the examiners in Part A, is ineligible to proceed to Part B, *and the fee which he has paid in respect of Part B is returned to him;*

and by the addition to Regulation 6 (regarding fees) of the following:

> If a candidate enters for Parts A and B of the examination on the same occasion, but owing to failure in Part A is precluded from sitting for Part B, five guineas of the fee paid in respect of Part B shall be returned to him.

Professor W. W. Jameson has been appointed to represent the University at the forty-second Congress of the Royal Sanitary Institute, to be held in Glasgow next July.

Applications for grants from the Thomas Smythe Hughes and Beaverbrook Medical Research Funds, allocated annually for assisting original medical research, must be sent in between April 1st and May 15th, 1931. Full particulars can be obtained on application to the Academic Registrar.

CHARING CROSS HOSPITAL MEDICAL SCHOOL

An Easter vacation course in applied anatomy and physiology will be held at the Charing Cross Hospital Medical School, W.C.2, from April 13th to April 17th. All the departments of the hospital and medical school will be open to those taking the course, which is intended for undergraduates studying for the examination in anatomy and physiology. The fee for the whole course is one guinea. Further information can be obtained from the dean of the medical school.

LONDON HOSPITAL MEDICAL COLLEGE

The Liddle triennial prize offered in 1929-30 has been awarded to William Evans, M.D., M.R.C.P. The subject of the essay for the prize was "The cause and incidence of duodenal ulcer."

UNIVERSITY OF GLASGOW

Professor A. Hunter has been appointed Dean of the Faculty of Medicine.

The following prizes have been awarded: Bellahouston Gold Medals, D. F. Cappell, E. M. Dunlop. Thomas Logan Memorial Medal and Prize, J. N. Davidson Kelly; *proxime accesserunt*, J. M. Hyslop and J. M. Watt. Macewen Medal in Surgery, W. S. Mack. Captain H. S. Ranken, V.C., Memorial Prize, W. M. Nichols.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A Council meeting was held on February 12th, when the President, Lord Moynihan, was in the chair.

Mr. Victor Bonney was re-elected the representative of the College on the Central Midwives Board for the ensuing year.

Fellowship

The Fellowship of the College was conferred upon Mr. R. W. Reid of St. Thomas's Hospital.

Diplomas

The diploma of Membership was conferred upon 149 candidates who had passed the examinations in medicine, surgery, and midwifery of the Examining Board of England.

Diplomas in Public Health were granted jointly with the Royal College of Physicians to nineteen successful candidates.

[The names of the recipients of the diplomas were printed in our issues of February 7th and 14th, pp. 250 and 292 respectively.]

Proposed Institution of Surgical Biological Research

A letter was read from Mr. G. Buckston Browne, F.R.C.S., offering to give to the College a sum of £50,000, and to add to it from time to time, for the purpose of building and endowing an Institution of Surgical Biological Research, in which surgeons, and particularly young surgeons, would have full opportunity for carrying out their investigations. Mr. Buckston Browne further offered thirteen acres of land at Downe, near Farnborough, Kent, on which the buildings could be erected, and where accommodation could be provided for the needs of the institution. The Council unanimously adopted the following resolution:

> That the Council hereby express their deep sense of Mr. Buckston Browne's great liberality, and on behalf of the College undertake to be responsible for the proposed Institution for Surgical Biological Research, subject to the settlement under a Deed of Trust of conditions satisfactory to the Council and to Mr. Buckston Browne.

Council Election

The President reported that an election of three Fellows into the Council would take place on Thursday, July 2nd next, at 11 a.m., in the vacancies occasioned by the retirement in rotation of Mr. J. Herbert Fisher, Mr. G. E. Gask, and Mr. Graham Simpson; that notice of the election would be given to the Fellows by advertisement and circular on March 6th; that March 16th would be the last day for the nomination of candidates; and that a voting paper would be sent on March 31st to every Fellow of the College whose address was registered at the College.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons this week carried a resolution authorizing a loan of £20,000,000 from the Treasury to the Unemployment Insurance Fund. A Bill to continue the Miners' Welfare Fund was also taken, and Supplementary Estimates for the Colonial and Middle-Eastern Services were put down for discussion. The House of Lords debated the Education (School Attendance) Bill.

Dr. Salter presided at a meeting of the Parliamentary Medical Committee on February 17th. The committee again discussed the proposed consultative committee for rheumatic clinics. It decided to report to Sir George Newman that the best type of consultative committee would be under the control of the Ministry of Health and modelled on the Cancer Committee. The Medical Committee also discussed the heads of a proposed Bill on proprietary medicines, but took no definite decisions. It will consult the British Medical Association on the subject. Recurring to marine hygiene, the committee considered the method of ensuring amenities for the crews on vessels now under construction. Dr. Morris-Jones and Mr. Somerville Hastings were left to put further questions in the House on this subject. Dr. Fremantle drew attention to the shortage of medical personnel in the Army, Navy, and Air Force, but no action was taken.

The Milk Supply

In the House of Lords, on February 10th, Viscount ASTOR called attention to the needs of the dairy industry and the necessity for stimulating the demand for British milk. To do that there must be publicity and propaganda, the cost must be reduced, and the hygienic quality and cleanliness of the milk improved. The Government should do something to encourage the giving of milk to children in the elementary schools. That would help the dairy industry and improve the health of the children. But if the nation was urged to drink more milk there must be a guarantee that the milk was reasonably safe and clean.

Lord MOYNIHAN supported Lord Astor's plea for a larger supply of milk, but, he said, with certain qualifications. Milk was rarely pure and was often contaminated, with the inevitable result that it caused a number of diseases. The supply of milk, therefore, was not the only problem. It was only when there was an acute outbreak of disease that the mind of the people was stimulated. Every day 100 people died from tuberculosis; and £250,000 was spent every day in this country alone on the treatment of tuberculosis, a large proportion of which was preventable. Of the 3,250,000 cows in this country giving milk, over 1,000,000 were tuberculous. What was to be done? A milk supply was very necessary. Were they to slaughter all the cows affected by tuberculosis? If that were done, it would be ineffective, except in so far as the immediate present was concerned. To immunize the animals would be a matter of great difficulty and uncertainty. The problem was whether the present conditions of our milk supply could be improved. One of the first methods was by boiling, which destroyed all organisms; it was easily available, and cost virtually nothing. There were, however, certain disadvantages in boiling; for though the nutritive value of milk was not diminished by it the vitamins were destroyed. The second method that could be adopted to make ordinary milk fit for human consumption was pasteurization; 90 per cent. of the milk in London and Manchester was pasteurized. A great deal depended on the human element in the process. It was essential that the machinery of pasteurization should be constantly supervised, and bacteriological control exercised at every stage. It was most desirable that the milk provided for pasteurization should be as pure as possible. Some inquiry further into the question of the milk supply was necessary, and it might be well if the Government set up a Royal Commission to reconstruct all the knowledge which had so far been obtained about the problem.

The EARL OF RADNOR said that there were no figures to show the amount of disease prevented by the consumption of milk. Milk was a very necessary part of the child's diet, and if it were withdrawn it was probable that the resultant diseases would be far worse than any diseases actually traceable to the consumption of tainted milk.

The EARL OF IVEAGH suggested that the Government should set up a committee of inquiry to bring up to date all the information available about milk. If they believed all that Lord Moynihan said then they would never drink a drop of milk again, at least unless it was boiled. At this moment, scientific opinion on milk was extremely divided. Such an inquiry should consider whether the evidence was for or against pasteurization of milk.

The EARL OF ONSLOW thought that the first thing necessary to increase the consumption of milk was to reduce the costs of production. If anything could be done to simplify the grading of milk it would be a great advantage.

Earl DE LA WARR said that he could not feel that the medical profession were entirely free from blame in this matter. One of the reasons why more clean milk was not produced in this country was the lack of demand. A great deal of Grade A milk to-day was sold as ordinary milk at ordinary prices. If the medical profession would talk a little less about dirty milk and do a little more to encourage the buying of clean milk which was already on the market they would be of more use to the nation as a whole and to the agricultural industry. They would also help the Government if they would decide what they really felt about milk. Before the medical profession came down on the farming industry for not taking certain steps about milk they should really make up their minds what they wanted the farmers to do.

Lord MOYNIHAN: We want you to produce pure milk. Until that is done we suggest that all milk should be pasteurized.

Earl DE LA WARR, continuing, said that he agreed that grade designations of milk were in an unsatisfactory state, but it was a very difficult problem to solve while there was so much disagreement in the industry. If the Minister of Agriculture could have some assurance of general support for a revision of these designations he would be glad to discuss the matter with the producers.

Mr. GREENWOOD, in reply to Mr. Lambert on February 12th, said that under the Imported Milk Regulations, 1926, imported milk must be free from tubercle bacilli. There was not the same risk from the presence of tubercle bacilli in milk products as in milk. Imported products were, in fact, no more likely to be infected than milk products of home manufacture. He would consider whether further measures should be taken to safeguard the public against the risk of tuberculosis from the consumption of milk products. So far as he was aware, the regulations for the control of imported milk were being carried out, but he would be interested to receive any information showing they were not.

Osteopathy Bill

A Registration and Regulation of Osteopathy Bill "to regulate the practice of osteopathy and to prescribe the qualifications of osteopathic practitioners" was read a first time in the House of Commons on February 11th without a division. Mr. W. M. ADAMSON introduced this Bill. He reminded the House that dentists, nurses, and architects—the last in a Bill then before a committee of the House—had asked for the privilege of dealing with their professional problems by their own organizations. His Bill asked a similar privilege for the osteopathic profession, so that they might be brought into line with the medical profession. The objects of the Bill were to establish a Board or Council with authority to regulate the practice of osteopathy in this country and to compile a register of practitioners of a prescribed standard. Osteopathy was a system of health and healing founded upon the fact that the body itself could provide the necessary qualities for health and healing, as long as it was kept in that mechanical adjustment that was essential for hygiene and other necessary conditions. In the United States forty-seven States had granted skilled osteopaths the privileges which this Bill requested.

Dr. FORGAN asked the House not to allow the Bill to be introduced. The conservative attitude of the medical

profession towards new methods had probably been beneficial to the community. Only a rash man would say that every registered medical practitioner had the skill or knowledge which some skilled osteopaths had, and it was unfortunate that some men with a natural bent or a wonderful pair of hands were prohibited from exercising that power for health which they might do if they were recognized. He did not oppose the Bill because there was nothing good in osteopathy, but because it was introduced on behalf of a section of osteopaths who were content with an education and training which would not guarantee that, if recognition were given, serious mistakes might not occur. Osteopathy concerned itself with far more things than the maladjustment of spinal vertebrae, and some osteopaths to-day in this country had four, five, or six years' training in their subject. There were also in almost every village bonesetters, who often did a great deal of harm, and men who had real skill and training should not be classified in the same category as their less fortunate brothers. He hoped the House, on a later occasion, would pass a Bill regularizing the best type of osteopathy.

The Bill, as stated above, was then read a first time. Further progress this session is not expected.

Prohibition Bill

Mr. SCRYMGEOUR moved the second reading of the Liquor Traffic Prohibition Bill in the House of Commons on February 13th. Clause 3 of this Bill provided that: "This Act shall not prejudice or obstruct the manufacture, importation, or sale of alcoholic liquors when intended to be used solely for scientific or industrial purposes. Alcohol, when required for medicinal purposes, shall be supplied only in bottles, labelled 'Poison,' by properly qualified medical practitioners, or by registered chemists. Further, chemists shall supply only on receipt of a medical certificate stating the maximum quantity to be supplied. Such sales shall be subject to the provisions of the Pharmacy Act, 1868."

Sir WILLIAM WAYLAND moved the rejection of the Bill.

Dr. FREMANTLE seconded the amendment to reject. The Bill was impracticable, and would put a brake on efficient measures which were bringing excess to an end. Excessive drinking accounted for 12 per cent. of the admissions to mental hospitals. In periodical inebriates 42 per cent. gave a family history of drink, insanity, or epilepsy. The habit of excessive drinking lowered resistance to disease, and in constant moderation it was liable to impair mental efficiency. Alcohol was the least dangerous of the drug habits because it was an open enemy. Its effects in themselves were deterrent and punitive, leading to preventive measures and restrictive action. Alcohol took little hold of the physically and mentally strong. The number of deaths due to alcohol, as shown by the Registrar-General, was something like 150 in the year; those connected with alcohol were 562, about one-third being in women. The number of such deaths per million inhabitants was 18 before the war, and came down to 2 in 1918. It went up to 6 in 1920, but was now rather under 4 per million inhabitants. Undoubtedly excessive drinking was being reduced very rapidly. In 1900 the arrests for drunkenness thoughout the country were 200,000; in 1928 they were only 60,000. Moderation and self-restriction had steadily increased during the past ten years, and the war had opened people's eyes to the national and personal value of health. A restrictive Bill would be a setback to that tendency.

Mr. LEIF JONES said that it was not easy for the medical profession to be outspoken on the effects of alcohol upon their patients.

Dr. FREMANTLE replied that the effects of alcohol were very difficult to diagnose. Doctors could not honestly certify more deaths as being definitely attributable to alcohol. The question of being under the thumb of patients and their friends had no substantial bearing on the figures.

Mr. SHORT stated that the Government could not give encouragement to the Bill until the Royal Commission on Licensing reported.

Mr. SOMERVILLE HASTINGS said that there were diseases and affections from which people who took alcohol suffered more than did the general population. In affections to which all were prone those who took alcohol suffered more severely and succumbed to a larger extent. Alcohol could be a very useful drug in the treatment of disease as a narcotic and sedative, though less used than formerly. The decrease in drunkenness was a matter for national congratulation, but occasional drunkenness was less serious than the regular taking of what some people would consider a relatively small quantity of alcohol. The Registrar-General showed for the years 1871 to 1929, in a series of curves, four things: deaths from alcohol and associated conditions, deaths from cirrhosis of the liver, deaths of infants from overlying, and the amount of spirits retained for home consumption in this country. All the curves went up and down in the same way; they ran parallel. All the four conditions increased to 1900, and after 1900 they decreased, with a rise about 1920 after the war, and a subsequent fall. The correspondence of the figures with the rise and fall of wages showed that people bought and used alcohol when their circumstances permitted.

The Bill was rejected by 137 to 18.

Shortage of R.A.M.C. Officers

On February 17th Major GLYN asked the Secretary for War whether, as it was necessary to employ 57 temporary and retired officers of the Royal Army Medical Corps, and as there was a deficiency of 124 in the authorized establishment, he would consult with the Admiralty and the Air Ministry to attempt to discover the cause of this shortage of medical officers under the present regulations. Mr. SHAW replied that he had the matter under his personal consideration, and was in close touch with his colleagues in regard to it.

Major GLYN: Is the right hon. gentleman satisfied that the conditions are satisfactory as regards medical officers? Mr. SHAW: No, I am not satisfied that the conditions are satisfactory; but unfortunately the difficulties in the way are not easy to surmount.

Dr. FREMANTLE asked whether this question had not been on the *tapis* for twelve years, and if it was not necessary now to take urgent action to deal with it. Mr. SHAW: There is one word that would solve the whole matter, and that is money; but unfortunately by the provision of money one might do more harm than good in respect to other officers in the Forces who are not medical officers. Dr. FREMANTLE: Does that mean that there is a total impasse? No answer was given to this question.

The Lübeck Tragedy: B.C.G.

Miss LAWRENCE, on February 17th, told Mr. Freeman that the Minister of Health understood that an official report had been made to the German Imperial Health Council concerning the deaths of sixty-seven children at Lübeck early in 1930 following the Calmette treatment of the Pasteur Institute. The council concluded that the deaths were not traceable to the original B.C.G. cultures, but were probably due to some unexplained admixture with virulent tubercle bacilli. The Imperial Council had also confirmed its decision of 1927 that the use of living bacilli, even in an attenuated form, for human prophylaxis was undesirable in the present state of knowledge.

Small-pox.—Replying to Mr. Freeman, on February 12th, Mr. GREENWOOD said that the ages of the seven children under 2 years who were reported to have died from small-pox in 1930 were, in two cases, 8 months, and in the other five cases 3 weeks, 18 days, 13 days, 1 month, and 7 weeks. The diseases, other than small-pox, which appeared on the death certificates were prematurity, jaundice, bronchial pneumonia, broncho-pneumonia, pertussis, and pyaemia.

Vaccination.—In a further reply to Mr. Freeman on February 12th, Mr. GREENWOOD stated that, during the year ended March, 1929, local authorities in England and Wales had expended £191,643 on the administration of the Vaccination Acts. The cost of the Government lymph establishment during the same period, after allowing for receipts from the sale of lymph, was £11,598. He had under consideration the whole question of vaccination, but could not promise to introduce legislation.

Notes in Brief

Mr. Greenwood told Mr. Freeman on February 12th that a health and nutrition advisory committee had been appointed to advise him on the practical application of modern advances in the knowledge of nutrition. He could not entertain the suggestion of appointing a nominee of the national vegetarian societies on this committee.

Medical News

At the invitation of the Metropolitan Counties Branch of the British Medical Association Dr. H. C. Cameron of Guy's Hospital will give the annual address to newly qualified medical practitioners and senior students in the Great Hall of the British Medical Association House, Tavistock Square, W.C.1, on Tuesday, March 10th, at 5.30 p.m. The subject of the address is "Children in hospital and in the home—a contrast; a lecture to young practitioners and senior students going up for the final."

Sir George Newman will deliver four lectures, entitled "Programme of the public service," at Gresham College, Basinghall Street, E.C.2, on February 24th, 25th, 26th, and 27th, at 6 p.m.; admission free.

The 158th anniversary dinner of the Medical Society of London will be held at the Trocadero Restaurant on Friday, March 6th, at 8 o'clock, with the president, Dr. R. A. Young, in the chair.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 60. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1. The list of special courses arranged for 1931 is now available.

The University of Sheffield has arranged for a series of post-graduate clinics on the cardio-vascular system from February 20th to April 24th, at 3.30 p.m. The clinics, which will be held at the Royal Hospital and the Jessop Hospital, are free to all qualified medical practitioners.

The post-graduate lectures and demonstrations on medical, surgical, and special subjects given by the honorary staff of the Manchester Royal Infirmary will be resumed on Tuesday, February 24th, when Dr. F. R. Ferguson will discuss disseminated sclerosis. They will be continued on Tuesdays and Fridays (except April 3rd and 10th) till May 19th. All the lectures and demonstrations commence at 4.15 p.m., and are free; tea will be served at 3.45 p.m.

At a meeting of the British Institute of Philosophical Studies, to be held at the Royal Society of Arts, 18, John Street, Adelphi, W.C., on Tuesday, February 24th, at 8.15 p.m., Professor John Macmurray will give a lecture on "Modern civilization and the moral ideal." A course of three lectures, entitled "Biology and social life," will be given by Professor Julian Huxley on Tuesdays, at 5.45 p.m., at University Hall, 14, Gordon Square, beginning on March 3rd.

Under the supervision of Dr. Maurice Chevassu a post-graduate course on diseases of the male genital organs will be held in the Cochin Hospital, 47, Rue du Faubourg-Saint-Jacques, Paris, daily from March 16th to 28th. In addition to numerous lectures and demonstrations there will be facilities for radiological, pathological, and cystoscopic work, and a diploma will be subsequently awarded to those who pass an examination on the subjects dealt with. The fee for the course is 500 francs, and further information may be obtained from Dr. Chevassu, Bacteriological Laboratory, Cochin Hospital, or from the Faculty of Medicine of the University of Paris.

The German Society for Combating Rheumatism has arranged a practical course in rheumatic diseases from March 2nd to 14th. The fee is 100 marks. Applications should be made to the secretary, Dr. Max Hirsch, Stieglitzerstrasse 66, Berlin, W.35.

The Halley Stewart Trust has provided freehold premises at Hampstead for an independent institute, the equipment of which will be shortly completed, where Miss Chevassut's research and the clinical work on disseminated sclerosis and kindred diseases will be continued in collaboration with a physician. The resources of this research institute will be open to all members of the medical profession and to all hospitals. Communications should be addressed to the secretary, Halley Stewart Trust, 30, Chesterford Gardens, N.W.3.

The People's League of Health announces that the Sims Woodhead series of thirteen constructive educational health lectures is being given in the board room of the National Union of Teachers, Hamilton House, Mabledon Place, W.C.1, on Mondays at 6 p.m. from February 16th to May 18th, excepting April 6th.

Dr. F. P. Sturm, aurist and laryngologist, Leigh Infirmary, Lancashire, has been elected an honorary member of "Le Carrefour de Cos."

Dr. Astley V. Clarke has been appointed vice-chairman of University College, Leicester, for the ensuing year.

The King has appointed Major H. J. H. Symons, *M.C.*, I.M.S., to be Vice-Consul at Bushire (with effect from November 6th, 1929), and Captain W. H. Critien, I.M.S., Vice-Consul at Seistan.

The King has confirmed the appointment of Dr. G. C. Strathairn (Director of Health) to be a nominated member of the Council of the Colony of Cyprus for a further period.

Dr. Kenrick Stanton Wise (Surgeon General) has been appointed a member of the Executive Council of the Colony of Trinidad and Tobago.

In 1930 the death rate in Madrid, which was the lowest for the last ten years, was 17.90 per mille, and the birth rate 27 per mille, the number of births exceeding the deaths by 7,503.

The number of medical women in Germany has increased from 82 in 1909 to 2,562 in 1929. In Berlin alone there are 476 women practitioners. In the various German medical faculties there are at present 3,428 female students. Since 1911 the number of female medical students has increased sevenfold, while that of the male students has only doubled. A memorial tablet has recently been affixed to a house in Quedlinburg, which was the birthplace of Dorothea Erxleben, the first German medical woman, who was born in 1715 and who qualified in 1754.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Majorca

"C. M." asks for information about the climate and diseases of Majorca. "Is there any water sanitation such as we understand it in England? Is the climate from October 1st to March 31st an eminently suitable one for patients who suffer from recurring chest colds or rheumatism, and who find the rigours of the Northern climes too severe? Book information is scanty, and it is difficult to give advice without adequate knowledge. The prevalence of both

mosquitos and flies, and in winter occasional cold winds of some severity, give rise to doubts as to the advisability of recommending Majorca as a winter resort for invalids or semi-invalids. Any first-hand information of recent date, with some indication of hotel prices in sterling, would be much appreciated."

Treatment of Sciatica

"G. W. I." writes, in reply to "BM/SRHH" (February 14th, p. 293): I have tried quinine and urea hydrochloride for sciatic pain with unsatisfactory results. Possibly my technique was faulty. But I have injected it for lumbago in a large number of cases, and I have rarely failed to give relief within a few minutes, and (strange to say) the freedom from pain persists.

Treatment of Syphilis

"F. G. V. S." writes: In reply to Dr. A. L. Pirrie's query (January 17th, p. 123) regarding the treatment of a persistent positive Wassermann reaction, I have treated several cases of this kind with intravenous injections of mercurosal (Parke, Davis and Co.). Not only is this preparation of high therapeutic value, but it has the following advantages: (1) there is no reaction, local or general; after an initial dose of 0.05 gram the full dose of 0.1 gram may be administered; (2) the convenient form in which it is supplied—in 5 c.cm. ampoules ready for immediate use. The course consists of twelve injections of 0.1 gram, given at intervals of three or four days. In every case that I have treated in this way a negative Wassermann reaction was obtained after the course. In view of the amount of treatment that Dr. Pirrie's patient has had, if the Wassermann is still positive after a course of mercurosal I should consider the case as one of the very few in which a permanent positive Wassermann reaction persists, and is not necessarily indicative of active syphilis, in which case further treatment would depend upon symptoms. Should Dr. Pirrie decide to try this treatment I should be interested to hear the result of the course.

LETTERS, NOTES, ETC.

Hypodermic Injection

Mr. CHARLES W. CATHCART, F.R.C.S. (Edinburgh), writes: The procedure of hypodermic injection was introduced for the first time in Scotland about the middle of the nineteenth century by Dr. Alexander Wood. The following details are taken from the account recorded in 1855 in the *Edinburgh Medical Journal*, vol. lxxxii. At that time neuralgic pains were treated by blisters and fomentations, but without much benefit. On that account Dr. Wood thought that he might give the patient relief by using a small syringe to inject a solution of morphine, through a hollow needle, down to the painful spot. With this object in view he wrote as follows.

"Having occasion, however, about the end of 1853, to endeavour to remove a naevus by injection with the acid solution of perchloride of iron, I procured one of the elegant little syringes constructed, for this purpose, by Mr. Ferguson of Gilt Spur Street, London. While using this instrument for the naevus, it occurred to me that it might supply the means of bringing some narcotic to bear more directly, than I had hitherto been able to accomplish, on the affected nerve in neuralgia. I resolved to make the attempt, and did not long lack the opportunity. . . . Miss ——, an old lady, who had long laboured under gastric and nervous symptoms, had suffered severely for four days from cervico-brachial neuralgia. This lady had the idiosyncrasy of not being able to take opium. Of this she had warned me, many years before she had first come under my care, and I never prescribed it for her. Under these circumstances I resolved to put in practice the plan which I had so long revolved in my mind. Accordingly, on November 28th, I visited her at 10 p.m. to give the opiate the benefit of the night. Having ascertained that the most tender spot was the post-clavicular point of Valleix, I inserted the syringe within the angle formed by the clavicle and acromion process, and injected twenty drops of a solution of muriate of morphia of a strength of about double that of the officinal preparation. In about ten minutes after the withdrawal of the syringe, the patient began to complain of giddiness and confusion of ideas. In about half an hour the pain had subsided, and I left her in anticipation of a refreshing sleep. I visited her again, about 11 a.m. on the 29th, and was a little annoyed to find that she had never wakened. The breathing also was somewhat deep, and she was roused with difficulty. Under the use of somewhat energetic stimuli, however, these symptoms disappeared, and from that time to this the neuralgia has not returned. In considering the modus operandi of this new application of remedial means, I think the following propositions will guide us to a right conclusion. Medicines when exhibited have usually two effects: (1) the local or topical, (2) the remote effects."

Glycerin as a Surgical Dressing

Dr. A. HAYES SMITH (Bradford) writes: As a contribution to the already lengthy correspondence on this subject, the following extract may be of interest. "Glycerin is a very good disinfectant, and acts extremely well if poured freely upon the dressing every two hours. If applied to wounds in large quantity from the first, it extracts so much water from the necrosed shreds of tissue that no foul smell arises; if decomposition has already set in it acts very slowly as a deodorizer; after three or four days' free application, wounds often become so red and sensitive that the use of it must be stopped." It is from Theodor Billroth's Lectures (vol. i, p. 233, eighth edition), published in 1877. The correspondence has added nothing to the knowledge contained in this paragraph regarding the value of glycerin as a dressing for wounds.

Teeth at Birth

Dr. A. SEGERDAL (Coalville, Leicester) writes: I have no doubt the following case is unusual, though not unique. The mother of a newborn baby noticed on the third or fourth day that it had two lower incisors. As the child was being breast-fed, the teeth began to irritate the mother's breast, and as one of the teeth was loose, I extracted a small decayed stump with a pair of dressing forceps. The other tooth, as it had not erupted much from the gum, I left. However, this tooth soon grew up from the gums and began to irritate the breast, so on the twenty-first day I extracted another loose decayed stump with an ordinary pair of dressing forceps. This second tooth had a longer fang than the first, and was not nearly so loose.

Unofficial Aunts

Mrs. E. W. HARDY writes from 7, Darley Avenue, West Didsbury, Manchester: May I appeal to all medical men and women to bear in mind the "Society of Voluntary Unofficial Aunts"? They stay in the house in charge of children, old people, and invalids, for an hour or two, thus enabling the one in charge to have a little free time. They also take women or children to the dental or other hospitals for treatment, thus helping and saving time and energy for many overworked mothers and daughters. The work is purely voluntary, without payment or subscription. I would ask medical practitioners who sympathize with the aims of the "V.U.A." to mention it in cases where they think we might be of use. An open meeting will be held on March 27th, at 3 p.m., at the above address, when the Lady Mayoress of Manchester will speak. Further particulars may be had from me.

The British Industries Fair

As announced in a recent issue of the *Journal*, the British Industries Fair, organized by the Department of Overseas Trade, is here again, at Olympia, London, until February 27th. Its big catalogue, with an index in nine languages, contains a description of the products of about twelve hundred firms of manufacturers (with eight hundred more showing at the fair simultaneously held in Birmingham). In the chemical section eighteen manufacturing houses are exhibiting analytical and research chemicals; twelve make the staple of their exhibit dyes and intermediates, and fifteen show drugs and pharmaceutical preparations. Medical and surgical instruments and appliances have a section to themselves, though not a large one. Only seven firms are showing *x*-ray and electro-medical apparatus, and a similar number surgical and ophthalmic instruments. But scientific instruments in general account for one of the largest group of exhibits, and in the provision of laboratory equipment and optical devices the British manufacturer is evidently well to the fore.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 52, 53, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54, 55, and 56.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 59.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

162 Epidemic Serous Meningitis

E. ECKSTEIN (*Klin. Woch.*, January 3rd, 1931, p. 22) states that in recent years there has been an increase in the number of cases of an affection of the nervous system which does not resemble any of the ordinary forms of cerebro-spinal disease. Clinical examination shows nuchal rigidity and Kernig's sign, but few other symptoms indicating cerebral localization apart from sluggish reaction of the pupil, unequal pupils, squint, and, rarely, facial paresis. On lumbar puncture the pressure is always increased, but the spinal fluid is clear, and only rarely turbid; it is invariably sterile. Gunther has collected 100 cases from the literature between 1908 and 1928. Epidemics of such cases have been observed by Wallgren in 1923; in New York and Boston by Brown and Symmers in 1925; in 1928 by Haessler in Leipzig, and also by Kaneko and Aoki in Japan in the same year. Eckstein himself has seen 13 cases of this kind between May and October, 1930, at the Düsseldorf children's clinic. The epidemic character of the attack is shown by the fact that six patients came from one suburb. The ages of the patients ranged between 10 months and 12 years. In six cases there was considerable increase in the tension of the cerebro-spinal fluid, while in the rest it was only slightly raised. In only two cases was the cell count above normal. Cultures of the fluid were all negative in each case. The whole of the children recovered after showing symptoms of more or less violent headache, vomiting, and, in the severe cases, nuchal rigidity. Apart from lumbar puncture, treatment was purely symptomatic. Eckstein agrees with Stoos in not regarding these cases as examples of poliomyelitis, since no instances of this disease occurred at Düsseldorf in 1930. On the other hand, Eckstein considers that epidemic serous meningitis is either an abortive form of encephalitis or a disease *sui generis*.

163 Sporadic Encephalitis

R. CITRON, R. SEIDMANN, and J. ZAPPERT (*Arch. f. Kinderheilk.*, November 28th, 1930, p. 39) classify 65 cases of encephalitis in children seen in hospital and private practice during the period 1920–29 into the following groups: 19 cases of typical epidemic encephalitis; 4 cases in which it was doubtful whether the diagnosis of epidemic encephalitis was correct or not; and 42 cases of other forms of encephalitis, including convulsive, meningeal, spastic, ataxic, tumour-like, bulbar, and myelitic. The typical cases of epidemic encephalitis continued to appear for some years after the epidemic and then entirely disappeared, no case having come under the authors' observation during the last four years. It is conceivable that the virus of epidemic encephalitis, in addition to causing an extensive epidemic, also has a special affinity for those parts of the brain involvement of which gives rise to the various forms of sporadic encephalitis mentioned. This hypothesis would explain the occurrence of numerous cases of encephalitis after the epidemic had subsided.

164 Lymphogranulomatosis in Children

The nature of lymphogranulomatosis being unknown, P. NOBÉCOURT, R. MARTIN, P. FOULON, R. LIÈGE, and J. STAVROPOULOS (*Ann. de Méd.*, December, 1930, p. 563) report three cases occurring in children, in the hope of elucidating its interrelation with tuberculosis. In two instances very large spleens were found. Since this organ is usually only slightly hypertrophied in lymphogranulomatosis, the finding proves that a marked splenomegaly does not eliminate the possibility of the latter. One patient presented an exceptional symptom, a chyliform pleurisy; guinea-pig inoculation with the effusion produced tuberculosis. Pruritus was not noted, and eosinophilia in the blood and tissues was also absent. These three cases, which are described in detail, exemplified the diagnostic difficulties encountered in certain atypical forms which, resembling the reticulo-endothelioses, can only be related to Sternberg's disease by the occasional appearance of the classical signs, the reticular and endothelial origin of Sternberg cells, the possibility of their mitosis, and the existence of cellular embolisms. The skin reactions are frequently negative to tuberculin (in 82 per cent. of cases) in children with lymphogranulomatosis. The involvement of the reticulo-endothelial tissue, the bacillary dissemination, and the granular cell changes lower the resistance and thus explain the frequent occurrence of associated tuberculosis.

165 Effects of Lead on Vision

F. G. PEDLEY (*Journ. Indust. Hygiene*, December, 1930, p. 359) comments on the effects of lead poisoning on vision, and reports a case of subhyaloid haemorrhage; he gives four other instances of eye involvement discovered among 100 cases of plumbism. He remarks that, since obscure eye disorders may occur in persons without any evidence of lead poisoning, it does not follow that an eye condition in a case of lead poisoning is necessarily due to this metal. Pedley's patient, a worker in lead aged 32, showed definite symptoms of plumbism, and was discharged to work after a month's treatment. Six months later he had an attack of severe pain in his left eye, which went rapidly blind; ophthalmoscopic examination revealed a typical subhyaloid haemorrhage. Six and a half months later the fundus was practically normal; only a few spots of brownish pigmentation were present, and this in spite of the fact that he had returned to work and still showed evidence of lead absorption. Although there were signs of arterial thickening, his blood pressure was normal, and renal function tests were negative. The author adds that the probability, statistically, of the plumbism and the subhyaloid haemorrhage having a causal relationship in this case is very strong, but the mere association of the two disorders does not constitute proof. In the other four cases—two of optic atrophy, one of neuro-retinitis, and one of probable retrobulbar neuritis—there was no positive proof that lead was the agent responsible for the conditions.

Surgery

166 Treatment of Post-Operative Colic due to Flatus

G. JEANNENEY (*Bordeaux Chirugical*, January, 1931, p. 46) calls attention to the fact that, following a reflex post-operative paresis of twenty-four to thirty-six hours during which gas accumulates in the intestines, the return of peristalsis is painful and the gas is expelled only after thirty-six or forty-eight hours. This slow expulsion is due to various causes: reflex intestinal paresis and spasms; absence of desire to defaecate owing to emptiness of the rectum; accumulation of intestinal gases; and the impossibility of efforts of expulsion due to tenderness of the wound. This condition may be prevented by omitting the usual active purgation on the eve of the operation, substituting for it a very light saline purgative two days earlier, or administering a small oily enema on the day before operation. A powder containing agar-agar and pulv. belladonnae promotes the absorption of gas in the large intestine. Rough handling of the intestines during the operation must be avoided. After the operation the abdominal wall should be anaesthetized with applications of a 20 per cent. solution of quinine-urea; drop rectal injections containing traces of laudanum should be given instead of morphine. Thirty hours later, peristalsis should be encouraged by hypodermic injections of pituitary

extract and of hypertonic serum. The very satisfactory results obtained by the serum led Jeanneney to try small enemas of concentrated saline solutions, with equally good results. In fatigued patients, one or two intravenous injections of hypertonic serum are also given. Rectal injections of hypertonic fluid cause a rapid reflex contraction, with relaxation of the sphincters and a quick evacuation of the rectal contents.

167 Low Backache

Discussing the etiology of low backache, C. W. B. LITTLEJOHN (*Journ. of the College of Surgeons of Australasia*, November, 1930, p. 201) calls attention to the number of cases in which it is caused by strains of the lower spinal articulations. The disability is too often prolonged by delay in instituting the appropriate treatment, by toxic absorption, and by the maintenance of a faulty posture. Good results usually follow appropriate treatment, which includes manipulation, postural exercises, the elimination of toxic foci, temporary fixation in plaster, and operative procedures. The author enumerates respectively the chief diagnostic points in sacro-iliac subluxation, sacro-iliac strain and arthritis, lumbo-sacral subluxation or spondylolisthesis, central and lateral lumbo-sacral strain, and transverse arthritis, and indicates the appropriate treatment in each instance. Factors which render this region of the spine particularly liable to injury are the adoption of the erect attitude, with the accompanying evolutionary changes; variation in the anatomical types; and the physical degeneration which accompanies civilization.

168 H. W. MEYERDING (*Journ. of Bone and Joint Surg.*, January, 1931, p. 39) considers subluxation of the lumbar spine a congenital or a traumatic factor in the etiology of pain in the lower part of the back and of deformity. It has been found to occur quite as frequently in men as in women, about 62 per cent. of the cases under review being in men. It may be caused by trauma, obesity, pregnancy, or occupational strain, and in many instances congenital defects, such as variations of the fifth lumbar vertebra and lumbar-sacral joint, were noted. In about 38 per cent. of cases the cause was ascribed to trauma, and the average age was found to be 37. Clinical signs of spondylolisthesis are lordosis with a shortened torso, and limited spinal motion and depression at the fifth lumbar vertebra with prominence of the upper posterior border of the sacrum. The chief symptom is backache, which is relieved by rest and aggravated by work; there may also be referred pain to the hips and legs. Neurological signs are usually paresis and modified sensation, limited as a rule to the fifth lumbar vertebra and the first sacral segment. Stereoscopic or lateral view *x*-ray photographs will aid the diagnosis. Treatment varies according to the condition and circumstances of the patient; in some cases a well-fitted body cast will give security and comfort. Obese patients require a corset with reinforced steel stays, while for those who must continue at work an operation is the most rapid and permanent treatment. This consists of fusion of the third, fourth, and fifth lumbar vertebrae and the upper part of the sacrum, by exposing the spinous processes and the laminae of these parts and using multiple bone grafts.

169 Treatment of Stone in the Solitary Kidney and Ureter

C. P. MATHÉ (*Surg., Gynecol. and Obstet.*, January, 1931, p. 79) states that the treatment of stone in the solitary kidney and ureter comprises many prophylactic measures such as the early removal of unilateral calculi and nephrectomy for calculus pyonephrosis; removal of all foci of infection in other parts of the body; the elimination of stasis in the upper and lower urinary tract; eradication of infection in the remaining kidney; and careful regulation of the diet and the life generally. Five cases are reported emphasizing the importance of the early removal of stone from the solitary kidney before renal insufficiency and advanced infection have set in. Early lithotomy on the solitary kidney and ureter is well tolerated, and followed by practically no shock. Cystoscopically controlled attempts to promote the passage of stones from the solitary renal pelvis or ureter are dangerous, since the stone may obstruct the ureter. In cases of chronic pyelonephritis this obstruction is likely to cause bacterial invasion of the parenchyma with resulting destruction of the kidney, anuria, uraemia, and death. Surgical removal of a stone from the solitary kidney and ureter requires exact technique and keen judgement. Preliminary drainage and lavage should be performed through the ureteral catheter. A wide incision to permit good exposure should be made; the kidney must be handled gently, the blood vessels safeguarded, and the incision in the pelvis and ureter left unsutured in order to ensure drainage. A combined pyelotomy and nephrotomy incision ensures removal of the stone and the tendency to recurrence is minimized. Decapsulation should be performed to avoid post-operative renal congestion.

Therapeutics

170 Treatment of Sprue

A. BASSLER and J. R. LUTZ (*Journ. Amer. Med. Assoc.*, December 27th, 1930, p. 1961) report ten cases of sprue in which gratifying results followed the combined employment of a high liver diet with fruits, vegetables, and milk product additions; transduodenal lavage is also strongly recommended. The correction of bacterial fermentation in the intestines is simultaneously effected, and residence in cool climates is arranged when possible. The authors found that their patients responded even better and more swiftly to liver treatment than is the case in pernicious anaemia, the proportion of ultimate recovery being higher also. They had obtained previously but little success with blood transfusion, injections of iron preparations, and various other forms of dieting. Transduodenal lavages with hypertonic saline solutions containing 9 grams each of sodium sulphate and chloride in a litre of water at 104° F. were used before bedtime to clear out the fermenting residue of the day's meals. As a rule the quantity introduced rarely exceeded 500 c.cm., and as improvement progressed the bulk or frequency of the washings was diminished. When practicable, cod-liver oil was added to the diet, with orange, pineapple, and other fruit juices, also tomatoes, lettuce, and fats.

171 Bacteriophage Therapy in Chancroid

J. J. A. BASSET (*Thèse de Paris*, 1930, No. 383) records seven cases of chancroid treated by injections into the buboes of a mixture of numerous bacteriophage strains which caused lysis of different varieties of streptococci, staphylococci, *B. coli*, *B. typhosus*, *B. paratyphosus*, and all other forms of lytic virus usually employed in laboratories. Compresses containing this mixture were also applied to the chancres. The results were encouraging, inasmuch as cure was obtained in the case of buboes after one to three injections in an average of eight days, whereas the chancres took much longer to heal. No general reactions resulted from the injections, but two patients showed a transient local reaction consisting in an aggravation of the inflammation.

172 Nirvanol in Chorea

O. R. TISDALL (*Arch. of Dis. in Child.*, December, 1930, p. 397) records conclusions based on the treatment of 29 cases of chorea with nirvanol and rest, no other form of medication being employed. The daily dose given by the mouth was 0.3 gram usually, but in 7 cases it was increased to 0.45 gram with no ill effects. Of the 29 cases, 15 completely lost their symptoms within six weeks; there was marked betterment in 9, and failure in 5. Of the 15 "cured" cases, however, 6 relapsed within six years or less, while 9 remained free from chorea permanently. Tisdall concludes, therefore, that nirvanol must not be considered a specific cure for chorea, although in acute forms its immediate results are encouraging. The heart remains unaffected by it. All patients should be confined to bed during the progress of treatment. Exposure to sunlight during the administration of nirvanol has been

reported by Keller to cause serious secondary reactions, but Tisdall found no such risk to be present in two cases in his series. He mentions, however, that a febrile reaction is usually present with a rash about seven to twelve days after the start of the administration; eosinophilia was an almost constant phenomenon, whether there was a noticeable reaction otherwise or not, and leucopenia was fairly common.

Neurology and Psychology

173 Etiology of Epilepsy

On the basis of his personal studies and data from the literature, D. M. OLKON (*Journ. Nerv. and Ment. Dis.*, November, 1930, p. 538) concludes that, in the vast majority of cases, genuine (or true) epilepsy is due to exogenic rather than endogenic influences, and that cerebral capillary haemorrhages are probably etiological factors. A study was made of the capillary systems of 17 infants delivered by Caesarean section, of a large number of others who had been delivered normally, and of many whose birth had been complicated by dystocia and forceps delivery; these last two complications gave rise to distortions of the cutaneous capillaries with capillary haemorrhage, while in the Caesarean section cases no such changes were detected. Even in infants born normally subcutaneous capillary haemorrhages were often present; they corresponded generally to the capillary changes noted in experimental animals. The more protracted and pathological the delivery process, the greater seemed to be the tendency to capillary haemorrhage. Experiments on 18 healthy dogs showed that a convulsion was followed by permanent sequels in the circulatory and respiratory systems. It is generally believed that genuine (or true) epilepsy may be caused by disturbances of metabolism, and that the metabolic derangement of the body and brain sets in early in epileptics. It is accepted that Jacksonian epilepsy is a sequel to cerebral trauma. Since Jacksonian and idiopathic epilepsy do not differ in the sum total of convulsive phenomena, Olkon considers that the latter may likewise be caused by trauma. Trauma, though not definitely observed, as in the Jacksonian type, with precise localization in the brain, is present nevertheless in the capillary system following dystocia and forceps delivery. Olkon suggests, therefore, that brain trauma sustained at birth, with its capillary haemorrhages, though slight, is adequate to give rise to the beginning of a metabolic imbalance in susceptible individuals and thus lead to the convulsive state.

174 Tumours involving the Cauda Equina

I. M. ALLEN (*Journ. Neurol. and Psychopathol.*, October, 1930, p. 111) reviews the clinical features and differential diagnosis of tumours of the cauda equina, the study being confined to those cases in which the presence, nature, and position of the tumour had been established either at operation or necropsy. A successful study of these growths depends on the separation of those in which the cauda equina alone is involved from those in which the conus and structures above it are also affected. The symptomatology of these tumours is described in detail; the importance of pain as the initial symptom is confirmed, and the fact is emphasized that pain in the back may be a more common initial symptom. Sudden and serious involvement of the sphincters at any stage of the disease indicates implication of the conus. Only in well-developed cases is any particular type of symptomatology found. Important points, however, are the asymmetrical character of the clinical findings, and the appearance of changes bilaterally in one or more subjective and objective sensations, motor functions, and reflexes. Diagnostic errors are chiefly made at the onset. Therefore, at this stage it is essential that ordinary clinical investigation be supplemented by special methods, particularly by a detailed examination of the cerebro-spinal fluid. When one or more physical signs are established, their bilateral distribution is suggestive; further investigations may be necessary to confirm the diagnosis and to localize the lesion. The results of treatment at different stages prove that success depends on early diagnosis. Delay in investigation and postponement of surgical measures till a clear clinical picture is present usually means waiting until the case is hopeless. The duration of the disease ranges from 3 months to 20 years from the onset, depending on the character of the tumour and the structures involved. The tendency of these tumours to affect the nerve roots in a haphazard manner is mentioned; the effect of this characteristic renders impossible a study of such neoplasms according to recognized syndromes. The various conditions from which tumours of the cauda equina must be differentiated are enumerated.

175 Juvenile Dementia Paralytica

W. C. MENNINGER (*Journ. Amer. Med. Assoc.*, November 15th, 1930, p. 1499) considers that juvenile dementia paralytica is the interaction of an immature, rapidly developing personality and a slowly progressing infection with early distortion, and later inhibition of development; eventually there is a breaking down of the complete biological unit. The existence of a "preparetic stage" is controverted, and asymptomatic cases are regarded as early dementia paralytica. A series of 40 patients, comprising 15 males and 25 females, is reported. The usual age of onset is between the 10th and 15th years; the duration of the disease ranges from two to ten years, averaging four years, which is longer than in the adult. Though the primary infection (usually syphilitic) may be acquired, all the cases under review were congenital. Most of the patients showed mental and physical retardation, and infantilism was a frequent symptom. Organic changes were more common and pronounced than in the adult; cranial nerve involvement and pupillary changes were greater and convulsions more frequent. Motor symptoms appeared earlier, and focal signs, such as hemiplegias and Jacksonian attacks, were more often obvious. All the cases tended to present the clinical picture of simple extreme dementia. Menninger remarks that the intellectual development depends on the patient's age when the cerebral damage becomes apparent: early, varying grades of feeble-mindedness are present; later, in all cases, deterioration or retrogression to dementia occurs. Treatment is without effect; presumably, the brain is so rapidly invaded, and the damage is so extensive, that the strongest therapeutic agents are ineffective, however relatively early they are employed.

Obstetrics and Gynaecology

176 Dangers of Cervical Caesarean Section

E. ROTTHAUS (*Zentralbl. f. Gynäk.*, January 10th, 1931, p. 89) and K. JÄGER (ibid., p. 94) describe cases illustrating respectively an immediate and a remote danger of transperitoneal cervical Caesarean section. In Rotthaus's case, one of placenta praevia, abundant venous haemorrhage occurred between the bladder and cervix as these were being separated, and proved fatal. Rotthaus recommends that in such circumstances, or when varices are present, the abdominal incision should be extended upwards and a corporeal section performed. In Jäger's patient, six years after cervical Caesarean section for placenta praevia, rupture of the pregnant uterus at term was diagnosed by palpation through the herniated abdominal scar; the classical signs were absent. Catheterization before operation gave issue to pure blood, and a large vesical tear had to be sutured after hysterectomy. The patient recovered. It is pointed out that clinical features of rupture of a "Caesarean scar" are frequently atypical and deceptive—in several cases the diagnosis having been first made at operation some days later; that more than 20 cases of uterine rupture in labour after cervical section have been reported; that this operation entails a special risk of rupture of the bladder as well as of the uterus in subsequent labours; and that during and immediately before these labours specially careful supervision is called for.

177 The Perivaginal Fascia in Nulliparae

B. H. GOFF (*Surg., Gynecol. and Obstet.*, January, 1931, p. 32) records a study of the perivaginal fascia in a nullipara, basing his conclusions on a classification of fascia into two types: the areolar, which surrounds and aids in maintaining the viscera, blood vessels, and nerves in normal positions; and the denser type which sheathes and unites the voluntary muscles. Goff found no fascia in the walls of the vagina, urethra, bladder, and rectum, and none between the anterior vaginal wall and the urethra. A thin layer of areolar fascia lies between the vagina and the bladder, and a similar layer between the posterior vaginal wall and rectum. These vesico-vaginal and recto-vaginal fasciae unite at the sides of the vagina to form the perivaginal fascia, which is part of the intrapelvic fascia. Its areolar character renders its dissection impossible as an individual layer, and its use as such in vaginal plastic operations. If used at all, it must be in conjunction with the overlying vaginal wall. No other fascia is available for use in the surgical correction of cystocele, rectocele, and urethrocele, and the successful treatment of these conditions depends on the utilization of the tissues of the vaginal wall rather than on the use of the fragile fascia which surrounds it. Goff believes that the adoption of the established histology of the tissues in and about the vagina, urethra, bladder, and rectum will lead to a clearer understanding of the problems of the conditions named above.

178 Haemorrhage in Delivery of Hydatidiform Mole

BAUX (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, November, 1930, p. 697) records the case of a 1-para, aged 23, who after four months' amenorrhoea was found to have albuminuria, oedema, and uterine enlargement corresponding to seven months' gestation; foetal parts or sounds were not detected. A diagnosis of hydatidiform mole having been made, it was found impossible on account of severe bleeding to introduce Hegar's sounds or a balloon. Two Krause bougies were passed into the uterus, but the cervix did not dilate, and bleeding from the womb continued to be alarming. Accordingly, Delmas's method of rapid accouchement under spinal anaesthesia was adopted as an alternative to hysterectomy. Full dilatation was rapidly secured digitally without difficulty or haemorrhage, and evacuation of the uterus was easy.

179 Chlorotic Anaemia of Pregnancy

M. B. STRAUSS (*Amer. Journ. of Med. Sci.*, December, 1930, p. 818) records three cases of the "chlorotic" type of pregnancy anaemia. All the patients had a chlorotic blood picture, and complete and persistent achylia gastrica; they responded well to iron therapy, and no other treatment was found necessary. The anaemia was clearly attributable to the pregnancy; the achlorhydria presumably prevented the absorption of adequate amounts of iron from the normal diet, and the additional strain of the pregnancy was more than the body could deal with.

Pathology.

180 The Relationship of Herpes Zoster and Varicella

A. NETTER and A. URBAIN (*Ann. de l'Inst. Pasteur*, January, 1931, p. 17) have for the last ten years been examining, by means of the complement-fixation test, the serum of patients suffering from herpes zoster, using as an antigen the vesicular fluid, or, better still, a suspension of the vesicular crusts. In the first 100 cases examined the serum was found to contain antibodies in 93 per cent. Over 150 cases have now been examined, apparently with similar results. More than half of the cases have been of the secondary type, occurring in the course of various local and general diseases, and intoxications such as arsenical or bismuth poisoning. No fewer than 28 of the patients with secondary zona were tuberculous. From the serological point of view there seems to be no difference between the primary and the secondary type; both lead to the development of specific antibodies reacting with the same antigen. With regard to the relation between herpes zoster and varicella, the authors have now collected over 230 observations on the development of one of these diseases after exposure to the other. The complement-fixation reaction has shown that the serum of patients with chicken-pox reacts to an antigen of zona crusts exactly as it does to an antigen of varicella crusts; conversely, the serum of a zona patient reacts equally well with an antigen of zona and of varicella crusts. This holds true not only for the serum of patients with primary herpes-zoster, but also for those with zoster coming on after encephalitis, vaccination, arsenical poisoning, and so on. The authors therefore conclude that the virus of varicella and of zoster are antigenically alike. The varicella virus appears to be more infective, and to leave behind it more solid immunity than the zona virus; these differences, however, are no greater than those between variola virus and vaccinia virus, which are known to be antigenically the same.

181 Enhancement of Infective Power of Bacteria

M. PIJOAN (*Journ. Exper. Med.*, January, 1931, p. 37) has confirmed and extended the work of Duran-Reynals, who showed the existence in certain organs of a substance that was capable of enhancing the infective power of staphylococci and vaccinia virus. This substance is present in greatest amount in extracts of the testicle and epididymis, but extracts of the kidney, skin, brain, and placenta are active to some extent. Extracts of retina, muscle, and ovary do not modify the infection, whereas those of blood, spleen, and bone marrow may interfere with, and even suppress, the activity of the infective agent. The Reynals factor is not species-specific. In the work now recorded it was found that the addition of testicular extract greatly increased the local lesion produced by the inoculation of numerous species of bacteria into the skin of mice and rats, and not infrequently led to a fatal result. Kidney extract, when tested with staphylococci injected intracutaneously into rabbits, proved to be less active; spleen extract led, on the other hand, to a certain diminution of the lesions, as compared with the Ringer controls. D. C. HOFFMAN (ibid., p. 49) found that the addition of testicular extract to suspensions of herpes virus, vesicular stomatitis virus, Borna virus, and vaccinia virus increased their pathogenic action very markedly. The Reynals factor enhanced the virulence of strong viruses; weak viruses behaved like strong ones. The vesicular stomatitis virus was rendered capable of infecting resistant species such as rabbits, or resistant tissues such as the abdominal skin of guinea-pigs.

182 Nephritis Caused by Trypaflavine

M. LEVRAT and A. BADINAND (*Journ. de Méd. de Lyon*, January 5th, 1931, p. 25) have studied the effects of intravenous injections of trypaflavine in rabbits. Intoxication is characterized by a rise in the blood urea content corresponding to the severity of the renal lesion, and a considerable degree of acute nephritis was invariably found. The uraemia appears to be due to the renal lesions, but it may be caused also by an excess of urea resulting from toxic disintegration of the tissues, especially of the muscles. The authors remark that an exhaustive investigation of the renal function in patients undergoing trypaflavine treatment is indicated, in order to determine whether the experimental results in rabbits are applicable to man; the recent publication of two cases of acute uraemic nephritis during trypaflavine treatment appears to suggest this possibility. Another investigator who used guinea-pigs has found intense glomerulo-nephritis, and in those which survived for a sufficient time there were extensive hepatic lesions. Apparently the toxicity of trypaflavine varies with the degree of purity. Levrat and Badinand find that the toxic effect was delayed, death supervening suddenly after a latent period of from four to seven days. They recommend a preliminary examination of the urine with a test of renal function, and that only moderate doses of trypaflavine should be used. Previous renal lesions may account for toxic symptoms supervening after the injection of moderate doses. Variations in the purity of the product are also important.

THE CONTROLLING FACTOR

OSTELIN
VITAMIN D

Liquid

Vitamin D in tasteless glycerin suspension for administration *"per se"* or for prescribing with other medicaments: should be included in all calcium prescriptions.

DOSE

Children ... ... 1-3 m.
Adults ... ... 3-10.

Tablets

Each tablet contains the vitamin D equivalent of 3 minims of Ostelin Liquid (or fluid drachm of cod-liver oil of maximum potency), together with 2 grams of soluble calcium glycerophosphate.

DOSE

One tablet 3 times a day.

INDICATIONS

"Ostelin" is indicated in the treatment of asthenias, hypotonic conditions, wasting, the anaemias, vasomotor skin disorders, chilblains as a prophylaxis against winter ailments.

VITAMIN D PROMOTES CALCIUM ABSORPTION

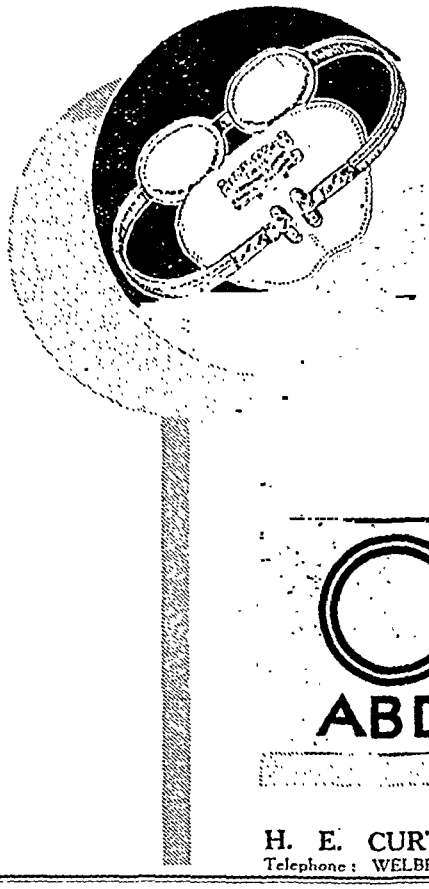
OSTOMALT is proving most useful as a tonic for adults convalescing from gastric or intestinal disorders—cases in which the routine type of tonic would not be tolerated.

OSTOMALT and "tonic" are synonymous. Whether the patient is infant, youth or adult, debilitated, convalescent or merely run-down, OSTOMALT will serve you well.

OSTOMALT

Ostelin Vitamin D, Malt Extract, Orange Juice, together with Calcium Glycerophosphate.

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1



Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

CURTIS
ABDOMINAL SUPPORT

Sole Manufacturers of the Curtis Appliances:—
H. E. CURTIS & SON LTD., 7, Mandeville Place, London, W.1.

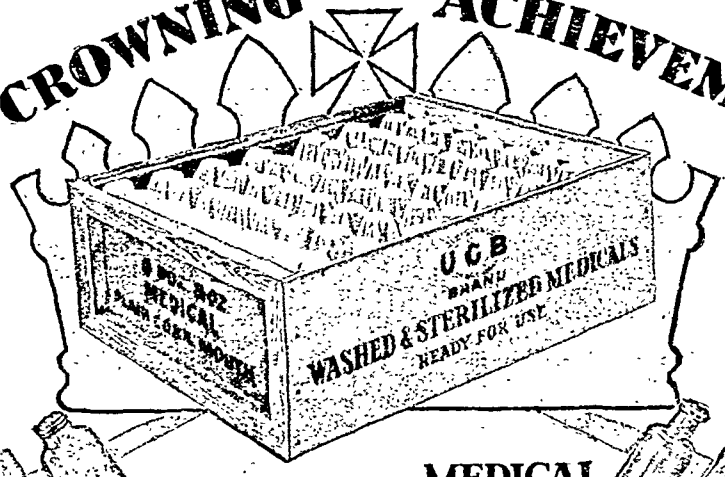
THE CROWNING ACHIEVEMENT



U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

UNITED GLASS BOTTLE MANUFACTURERS · LIMITED
The largest manufacturers of Glass Bottles in Europe.

"The Rose Corset-Belt"
for Accurate Abdominal Support and Comfort
Extract from the "British Medical Journal," Dec. 10th, 1927—
"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

RE-INFORCING THE ABDOMINAL MUSCLES WITHOUT UNDUE PRESSURE!

For those disorders of the abdomen that call for external support, Domen Abdominal Belts have very definite advantages. They give adequate support to the abdomen without setting up pressure to aggravate the patient's condition. And whether it is pregnancy or umbilical hernia, prolapsus uteri, or simply general support, there is a Domen Belt designed specifically for that condition. Domen Belts fit well, sit comfortably and do not get out of place. They leave the patient free and without embarrassment. Full particulars will be forwarded on receipt of your card or a telephoned request.

A NON-HABIT FORMING ELIMINANT

Sal Hepatica possesses all the essential qualities of the perfect purgative. Its action is prompt, painless and thorough. It is non-habit-forming, because it contains sodium phosphate which increases bile secretion—thereby avoiding the habit-forming propensities of other laxatives that call for steadily increasing doses. The exhibition of Sal Hepatica is by far the most pleasant and effective means of eliminating all toxic amino acids from your patient's system and ensuring regular defecation. Sal Hepatica is an efficient eliminant, antacid, cholagogue and diuretic.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Co.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Sal Hepatica

the proved, medicinal, saline laxative & cholagogue.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

County Council of Durham.

EDUCATION DEPARTMENT.

ASSISTANT SCHOOL MEDICAL OFFICER.

The County Education Committee invite applications for the post of Assistant Medical Officer, to act under the School Medical Officer in connection with the inspection of school children, and such other duties as may be required by the Education Committee. Commencing salary £500 per annum (providing the candidate has had not less than three years' Post-Graduate experience), rising by annual increments of £25 to £700 per annum, together with travelling expenses according to the County Scale. The successful candidate will be required to devote his (her) whole time to the duties of the office, and reside in or near the district to which he (she) will be attached at a place to be approved by the Education Committee. The appointment will be subject to three calendar months' notice on either side, expiring on the last day of any calendar month. Applicants must have had experience in the work of school medical inspection, and preference will be given to candidates who:

(a) Have had experience in the work of School Clinics.
(b) Have been accustomed to make special reports on Mentally Defective, Physically Defective, Epileptic, and other Defective Children.

The possession of a Diploma in Public Health is desirable, though not essential.

Copies of not more than three recent testimonials are required.

Canvassing, directly or indirectly, is prohibited, and will disqualify.

A deduction of 5 per cent. will be made from the salary in accordance with the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the County Council's medical examination in connection therewith.

Forms of application, to be returned not later than Saturday, February 28th, may be obtained from the Director of Education, Shire Hall, Durham, on receipt of stamped addressed envelope.

Shire Hall, Durham. THOS. B. TILLEY, Director of Education.
February 9th, 1931.

Metropolitan Borough of Woolwich.

[illegible] from registered [illegible] the appointment of [illegible] OFFICER in the Public Health Department.

The appointment is a whole-time one, and the officer appointed will be required to carry out, under the supervision of the Medical Officer of Health, such duties under the Council's Maternity and Child Welfare Scheme, and the Council's Tuberculosis Scheme, as may be required from time to time by the Council. Applicants must have had adequate experience in these duties.

The appointment, which will be during the pleasure of the Council, is subject to the approval of the Ministry of Health and the London County Council, to the By-laws and Regulations of the Borough Council, and to termination by one month's notice on either side.

The salary, which will include all fees and emoluments, will be £600 per annum, rising, subject to the approval of the Minister of Health, by annual increments of £25 to £700. No bonus will be paid.

Applications, on a form to be obtained from the Medical Officer of Health, Town Hall, Woolwich, S.E.18, and accompanied by copies of not more than three recent testimonials, must be received by me not later than the first post on March 5th, in an envelope endorsed "Assistant Medical Officer."

Canvassing, either directly or indirectly, any member or officer of the Council, will disqualify.

County Offices, Wick. JAMES ROBERTSON, County Clerk.
February 12th, 1931.

Borough of Reigate.

MEDICAL OFFICER OF HEALTH, SCHOOL MEDICAL OFFICER, AND MEDICAL OFFICER OF INFANT WELFARE CENTRE.

The Reigate Town Council invites applications from duly qualified persons of not more than 35 years of age, holding a Diploma in Public Health and possessing Municipal or Local Government experience, for the appointment of Medical Officer of Health, School Medical Officer, and Medical Officer of the Infant Welfare Centre for the Borough.

The total commencing salary will be £800 per annum, with an allowance of £40 per annum for travelling and other expenses.

The person appointed will be required to devote his whole time to the duties of his offices, and must reside within the Borough. The duties to be performed are those defined by the Sanitary Officers Order, 1926, made by the Minister of Health, together with any other duties which may from time to time devolve on a Medical Officer of Health by virtue of any present or future Act of Parliament or Orders or Regulations of the Ministry of Health.

He will also be required to act as School Medical Officer and Medical Officer at the Infant Welfare Clinic.

The officer's tenure as Medical Officer of Health will be governed by Section 1 of the Public Health (Officers) Act, 1921.

The Council will provide offices and staff.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be sent, endorsed "Medical Officer," so as to reach me not later than Friday, March 13th next.

Twelve copies of the application and testimonials should also be forwarded for the use of the members of the Committee.

Canvassing in any form is strictly prohibited and will disqualify.

By Order of the Council,
Municipal Buildings, Reigate. ALFRED SMITH, Town Clerk.
February 14th, 1931.

City of Birmingham.

SELLY OAK HOSPITAL.

MALE RADIOGRAPHER.

Applications are invited from fully qualified Radiographers for the above whole-time appointment.

The scale of salary will be £250 per annum, rising, subject to satisfactory service, by annual increments of £20 to a maximum of £350 per annum. The commencing salary will be placed within this scale according to qualifications and experience.

The appointment will be subject to the Birmingham Corporation's Superannuation Scheme, and to the candidate passing a medical examination, and will be subject to one month's notice on either side.

Further particulars of the appointment may be obtained from the Medical Superintendent, R. P. S. KELMAN, Esq., M.B., Ch.B., F.R.C.S. Eng. and Edin.), to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Wednesday, March 11th.

The Council House, Birmingham. F. H. C. WILTSHIRE, Town Clerk.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be addressed to the undersigned not later than March 7th.

City Hall, Cardiff. RALPH M. F. PICKEN, Medical Officer of Health.
February, 1931.

City of Bradford.

MUNICIPAL GENERAL HOSPITAL, ST. LUKE'S

HOUSE PHYSICIANS and HOUSE SURGEONS required.

Salary in each case £200 per annum, plus board and lodgings.

These appointments are for six months, renewable for a further period of six months.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to him not later than February 28th.

Town Hall, Bradford. N. L. FLEMING, Town Clerk.
February 9th, 1931.

Metropolitan Borough of Poplar.

MALE ASSISTANT MEDICAL OFFICER OF HEALTH (TUBERCULOSIS SECTION).

The Council of the Metropolitan Borough of Poplar invite applications for the above post from duly qualified and registered male Medical Practitioners who are specially qualified in the diagnosis and treatment of Tuberculosis, and not over 40 years of age.

The person appointed will assist the Tuberculosis Officer, and, when necessary, carry out other duties in the Public Health Department under the direction of the Medical Officer of Health, and devote his whole time to the services of the Council.

Applicants should have:

(1) At least three years' experience in the practice of his profession; (2) spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as a resident officer in charge of beds occupied by general medical and surgical cases; and (3) received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

A Diploma in Public Health is desirable.

The commencing salary will be at the rate of £600 per annum, rising by four annual increments of £25 to £700 per annum.

The successful candidate will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Forms of application may be obtained from my office, and must be returned, together with a letter of application and copies of three recent testimonials, in envelope endorsed "Male Assistant Medical Officer of Health," not later than Friday, February 27th instant.

Canvassing members or officers of the Council, in any form, will disqualify.

Council Offices, Poplar, E.14. H. E. DENNIS, Town Clerk.
February 10th, 1931.

County Council of Middlesex.

DISTRICT MEDICAL OFFICER AND PUBLIC VACCINATOR.

The County Council invites applications from duly qualified Medical Practitioners for the undermentioned appointments:

DISTRICT MEDICAL OFFICER, ISLEWORTH (part of).

Salary £140 per annum, rising by annual increments of £7 10s. to £180 per annum. The officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district, and to name to the Council some duly qualified Medical Practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

PUBLIC VACCINATOR, ISLEWORTH (part of).

The person appointed will be required to produce to the Council a certificate of proficiency in vaccination, unless such certificate was required as a condition of obtaining any diploma, licence, or degree which he possesses.

He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the minimum fees laid down in the Order.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than March 7th.

No special application forms are provided. Envelopes must be endorsed "District Medical Officer" or "Public Vaccinator," as the case may be.

Canvassing, directly or indirectly, will be a disqualification.

Guildhall, Westminster, S.W.1. ERNEST S. W. HART, Clerk of the County Council.
February 10th, 1931.

Margate and District General Hospital. (80 Beds.)

[illegible] invited for the post of [illegible] FICER (male) to commence 2nd next. Twelve months' engagement (renewable).

Salary £125 per annum, with board and laundry.

Applications, accompanied by copies of testimonials, should be sent to the Secretary, Medical Committee, at the Hospital, as early as possible.

Lowestoft and North Suffolk Hospital, Lowestoft.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the **British Medical Bureau** is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the **British Medical Bureau.** Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the **British Medical Bureau** to ensure that only the most **Trustworthy and Reliable** Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the **British Medical Bureau.** A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The **British Medical Bureau** has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

THE TUBERCULOSIS DANGER!

It has been stated in Parliament that *over two thousand children die every year through tuberculous milk.* How many children who survive grow up weaklings through the taint of bovine tuberculosis? This hardly bears thinking about. Cow & Gate Milk Food is guaranteed absolutely free from tuberculosis and other pathogenic organisms.

Read the following extract from the Presidential Address at the Royal Sanitary Institute Congress at Margate, it is of vital significance to the medical and nursing professions:

"The loss on the agricultural and veterinary side of 52,222 bovines during the three years 1926, 1927, 1928, slaughtered under the Tuberculosis Order of 1925, and at least twice that number not reported but otherwise disposed of, the estimate that 40 per cent. of the cows of our dairy herds producing milk for human consumption are tuberculous, are circumstances in themselves that demand immediate attention. But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended. It is no credit to us as scientists and protectors of public health that such a state of affairs should be permitted to continue, or even to exist."

-IS SAFE!

Another remark made at the meeting was as follows:

"It would be better to have no milk supplied at all than to feed children on diseased milk as is being done at present."

Cow & Gate Milk Food

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins unimpaired. It is a basic milk food which can be modified by the profession as they desire to suit each and every case.

The Treatment of

Rheumatism,
Sciatica, Lumbago,
Gout, Neuritis, Arthritis, etc.,

with

AGOTAN

Brand

(PHENYLCINCHONINIC ACID)

Reports from eminent Medical Men show that **AGOTAN** brand Phenylcinchoninic Acid B.P.C. is remarkably successful in the treatment of Rheumatoid conditions due to excess of Uric Acid. Under the influence of **AGOTAN** Uric Acid is eliminated from the blood so rapidly that its deposition in joints, etc., is prevented or much reduced, thus avoiding or quickly removing *local* manifestations.

7½ grain tablets, also powder, and in tubes for local application.

Influenza
and the
Common Cold

The New Quinine Salt QUININE BI-SALICYLO-SALICYLATE known as

QUINISAN
(HOWARDS)

is proving a remarkable remedy.

In many cases the heaviest cold is completely eradicated

WITHIN 36 HOURS.

As regards INFLUENZA, an eminent medical man writes:—

"The effect (of QUINISAN) was so remarkable, that attacks of Influenza which began on the first day with shivering and temperature up to 104° F. and which were treated about midday, only showed a little over 98·6° F. on the following morning and were entirely free from fever and all discomforts by the afternoon. These observations are based on 50 cases.

Quinisan had no unpleasant by-effects and when administered in the first 24 hours is an absolutely reliable remedy for cutting short the attacks."

4 grain tablets in bottles of 25 and 100.

Samples will be sent to any Medical Man on applying to

London: 40, Gloucester Place, Portman Square, W.1

THE METABOLISM OF TUMOURS

Investigations from the Kaiser Wilhelm Institute for Biology, Berlin-Dahlem

Edited by

OTTO WARBURG

Lancet:—". . . the translation is excellent, and the English edition will make a strong appeal to all those who wish to use the manometric technique in the study of chemical reactions, since its theory and practice are described in great detail."

British Medical Journal:—"The researches have added an important detail to our knowledge of the peculiar features of tumour growth—a valuable acquisition, since it opens up a new avenue of approach in the study of the causation of tumours."

Translated by FRANK DICKENS, M.A., Ph.D.

Vaho-Cresolene Est. 1879

Sold by Chemists

Write for descriptive Booklet No. 29.

WHOOPING COUGH

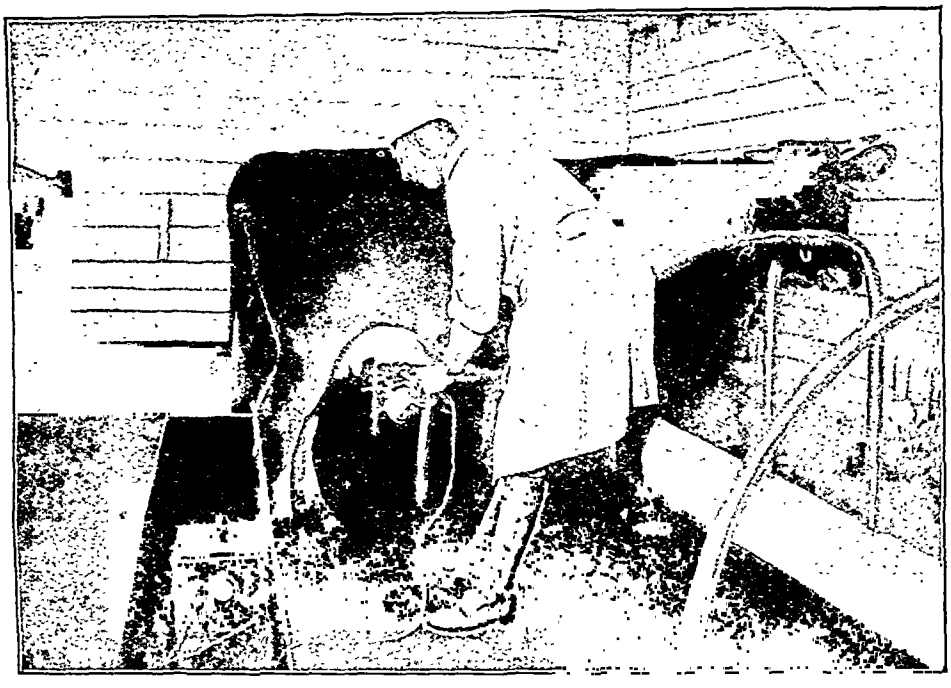
The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

MICKLEFIELD IRRADIATED MILK



TREATING THE COW

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

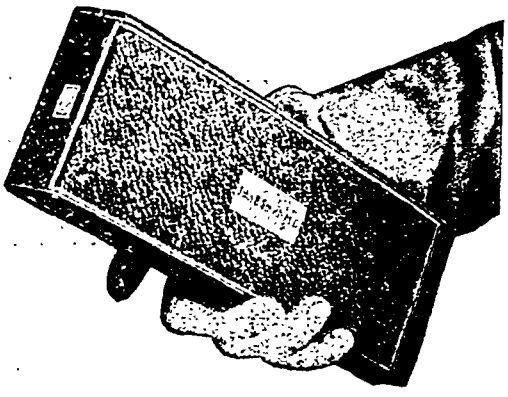
(1) Average increase in height '605-in. (2) Average increase in weight 9.72 ozs. more than (1).
(2) " " " '610-in. (3) " " " 10.9 ozs. more than (1).
(3) " " " '744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every week-day in London; elsewhere by arrangement.

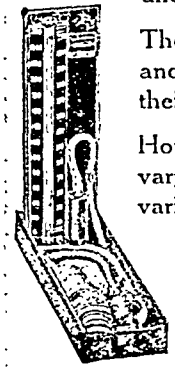
Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

NEW **KOMPAK** MODEL



Lifetime Baumanometer
STANDARD FOR BLOODPRESSURE

Physicians who use aneroid blood pressure gauges nowadays don't expect them to be accurate to the millimeter, because they understand the nature of such instruments.



They try to establish the degree of variation and make allowance for it when taking their readings.

However, an instrument that concededly does vary may easily show a different degree of variation from one reading to another.

In cases where regular check-up of the patient's blood pressure is necessary, the unvarying accuracy of the Baumanometer is indispensable.

Obtainable from leading Surgical Equipment Houses, or
HAWKSLEY & SONS, Ltd., 83 Wigmore St. London, W. 1.

SMALLEST

SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

How Saltair Surgical Service assists the Medical Man

Saltair Surgical Service is a thorough Service of incalculable value to Medical Men.

- It enables them to order an appliance which will be specially made to the patient's requirements and to select the quality from a wide range of prices and materials.
- Comprehensive catalogues, embodying simple order forms, enable the Medical Man to prescribe in detail the type of appliance needed to meet the case.
- Finally—should the appliance supplied, for any reason be found unsuitable, it will willingly be accepted back or exchanged under the terms of our famous Guarantee.

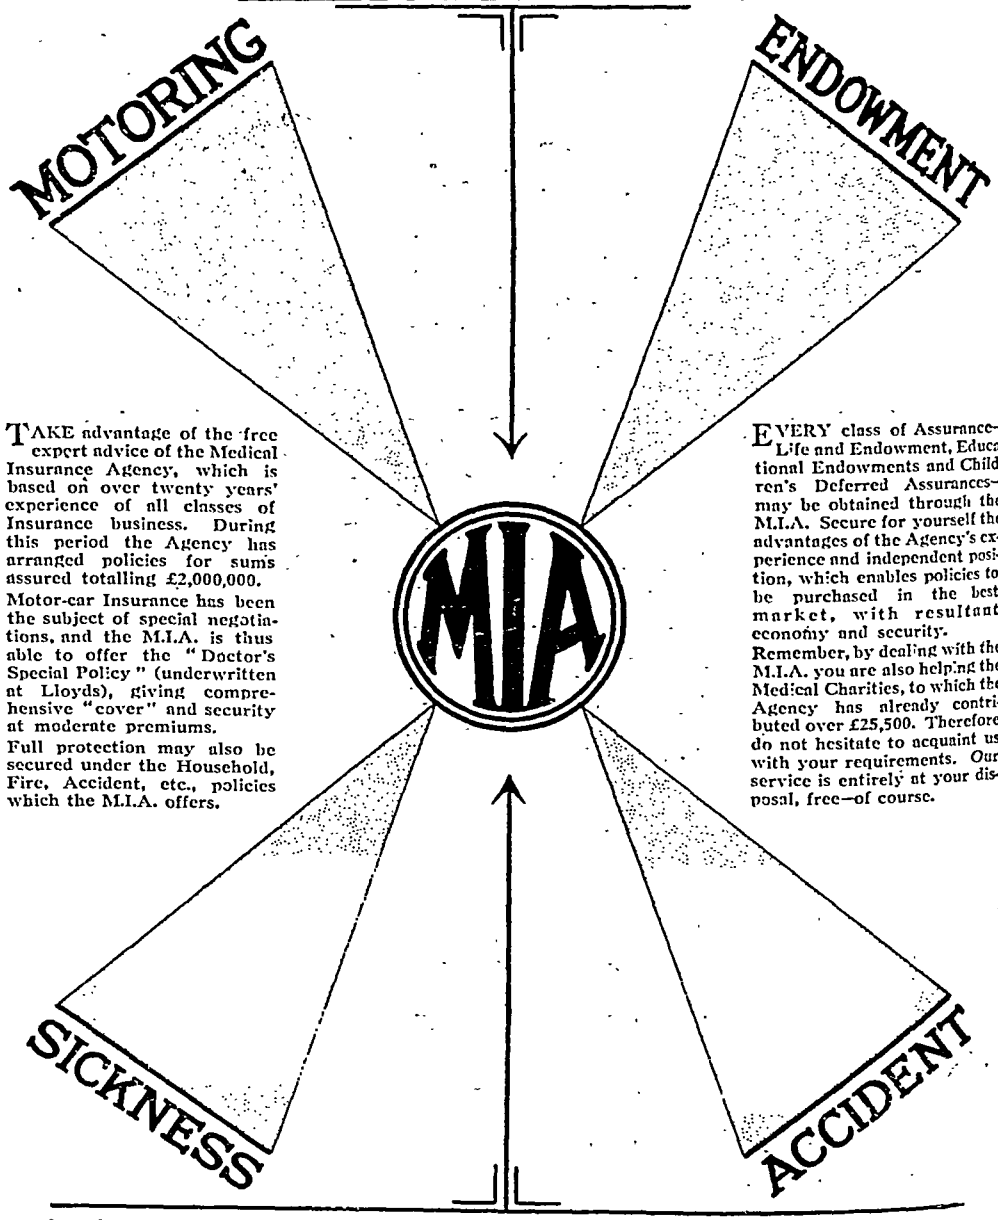
Insurance



TAKE advantage of the free expert advice of the Medical Insurance Agency, which is based on over twenty years' experience of all classes of Insurance business. During this period the Agency has arranged policies for sums assured totalling £2,000,000.

Motor-car Insurance has been the subject of special negotiations, and the M.I.A. is thus able to offer the "Doctor's Special Policy" (underwritten at Lloyds), giving comprehensive "cover" and security at moderate premiums.

Full protection may also be secured under the Household, Fire, Accident, etc., policies which the M.I.A. offers.

EVERY class of Assurance—Life and Endowment, Educational Endowments and Children's Deferred Assurances—may be obtained through the M.I.A. Secure for yourself the advantages of the Agency's experience and independent position, which enables policies to be purchased in the best market, with resultant economy and security.

Remember, by dealing with the M.I.A. you are also helping the Medical Charities, to which the Agency has already contributed over £25,500. Therefore do not hesitate to acquaint us with your requirements. Our service is entirely at your disposal, free—of course.

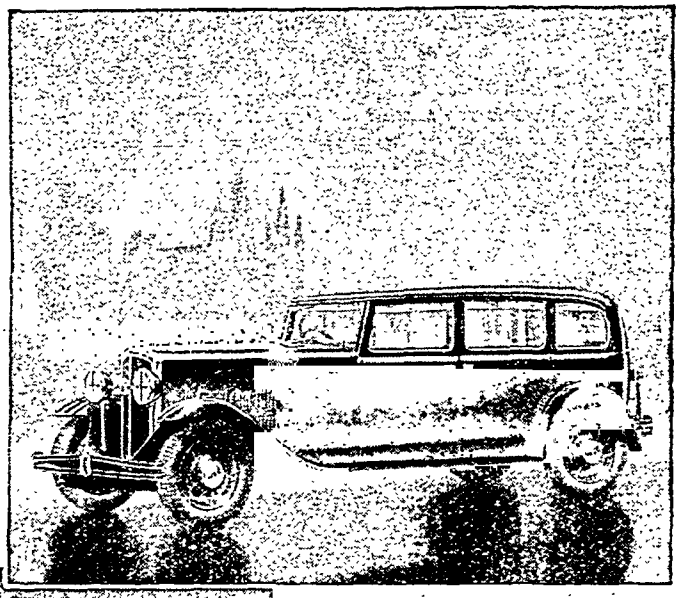
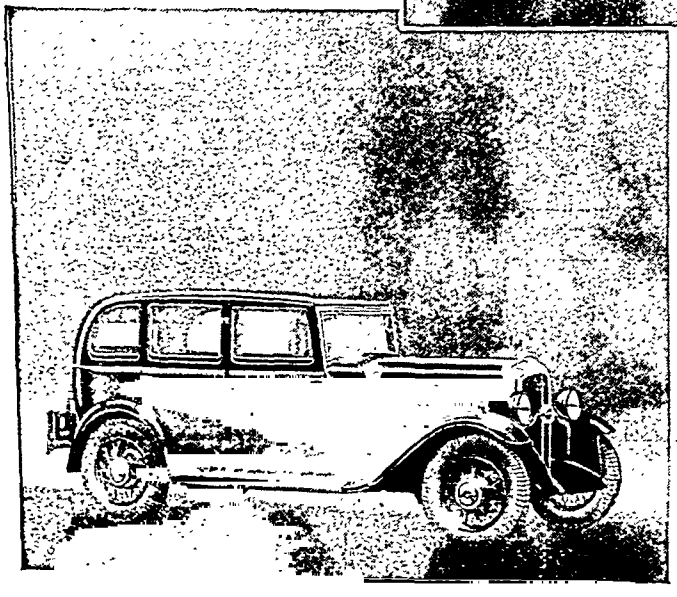
Rover offer a range of cars for every phase of medical service

FROM the distinguished Meteor Limousine to the popular Rover Family Ten there is a Rover model that can, and does, serve every phase of a doctor's duties. The Limousine for the Consultant, securing privacy for the conference en route with colleagues: the Two Litre Six or Light Twenty for the scattered and difficult country districts: the Family Ten for easy manipulation in mean and narrow city streets and in congested traffic—and in each power grade a matchless performance.





WE illustrate two models. The top one is the Meteor Limousine—it has a drop down division that can be closed for professional purposes and opened on social occasions. It costs only £548 and gives dignity, power, and comfort at extremely low cost. The illustration left is the Rover Family Ten offering exceptional passenger accommodation, well sprung and comfortable so that an emergency run with patients requiring almost 'stretcher' length can be easily arranged. It will achieve 60 miles per hour, has run 2,147·2 miles for £5 under official observation. Brief particulars of the price are supplied on the left.

Rover Family Ten—from £189 | Rover Light Twenty—from £358

Rover Two Litre—from £298 | Rover Meteor—from £398

Rover Meteor Limousine £548

Guaranteed by the maker for Two Years, supervised by the seller for Two Years

FOR INTERNAL TREATMENT OF GONORRHOEA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.
There is marked absence of gastric and other disturbances, diarrhoea and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or tolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhoea and in other forms of Urethritis and affections of the Genito-Urinary tract.
The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Virienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2

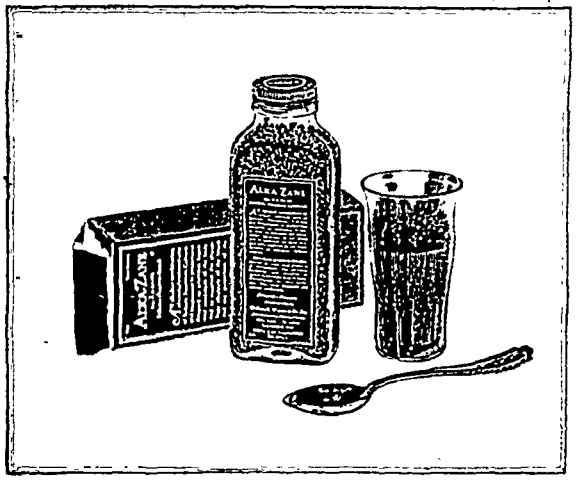
JB 91

Rational Alkaline Medication



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

must be adapted to the physiological requirements of the human organism, in order to neutralize excess acid products and restore alkaline balance, without the risk of intoxication.
A trial will promptly convince you of the value of Alka-Zane as antacid, diuretic, and to restore normal alkalinity, in gouty and rheumatic conditions, gastric or intestinal hyperacidity, and in certain skin diseases.

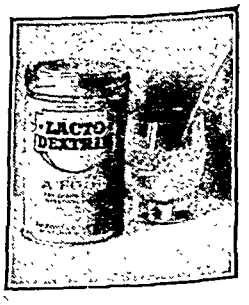
TWO NEW PREPARATIONS

Vide THE LANCET, Jan. 10th, 1931.

"PSYLLA (psyllium seed); LACTO-DEXTRIN (Battle Creek Food Company, Mich., U.S.A., Distributing Agents, Coates & Cooper, 41, Great Tower Street, London).—This company have sent us specimens of their laxative agent, Psylla, and their preparation, Lacto-Dextrin, for use in intestinal toxaemia. Psyllium seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in Fissure or Haemorrhoids. The same firm has received favourable reports from the clinical use of their combination of lactose and dextrin."—*Lancet*, Jan. 10th, 1931.



Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

PSYLLA
(Psyllium Seed)

LACTO-DEXTRIN

Products of the BATTLE CREEK FOOD CO., Mich., U.S.A.

CAPROKOL

The urinary antiseptic that gives immediate symptomatic relief and continuously disinfects until the whole urinary system becomes sterile is an ideal one for both patient and physician; hence the adoption of Caprokol by numerous practitioners as a matter of routine.

These beneficial effects following the administration of Caprokol in urinary tract infections are the direct outcome of its soothing analgesic action upon the mucosa of the urinary tract, and of its highly-bactericidal character. Moreover, its ease of administration and its freedom from objectionable odour add not a little to its acceptability from the point of view of the patient.

Capl34

CEREBRO-SPINAL MENINGITIS

During epidemics, or seasonal rise of prevalence, many become CARRIERS of the
MENINGOCOCCUS,
the causative agent, in the Nasopharynx.

Disinfection is then the best method of protection from attack.

Of all disinfectants

DIMOL SNUFF

is the most—

CONVENIENT . . . . In powder form in neat pocket containers, available for use at any time, anywhere, without trouble.

EFFICIENT . . . . . Even when diluted with **10 times its bulk** of mucus, Dimol Snuff
KILLS IN 32 SECONDS
the meningococcus, the cause of the condition.

By the nature of the snuff, by which it becomes sticky in the presence of moisture, it adheres to the mucus of the nasopharynx and becomes dissolved. Unlike liquids, the action is therefore long continued.

Prices and particulars will be sent on application to

DIMOL LABORATORIES, LTD., 40, LUDGATE HILL, LONDON, E.C.4.

INSULIN 'A.B.'

TRADE A B MARK

80 Units per c.c.

Insulin 'A.B.' is now available in a concentration of 80 units per c.c., or four times the normal strength, for the convenience of large dose administration.

Supplied in three strengths:

20 units per c.c. Packed in bottles containing:
5 c.c. (100 units or 10 doses) 2/- each
10 c.c. (200 „ 20 „) 4/- „
25 c.c. (500 „ 50 „) 10/- „

Bethnal Green, London, E.2

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occation offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

SONERYL

TRADE MARK

Powerful Hypnotic and Analgesic

An agent which has the double advantage of relieving pain and inducing sleep is invaluable in everyday practice.

"Soneryl" adequately meets this need and is widely employed for insomnia, whether arising from painful affections or febrile or nervous states.

"Soneryl" produces no after-effects nor does it lead to habit formation.

Supplied in tablets for oral use and ampoules for intravenous or subcutaneous injection

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.
Works: KING'S LANGLEY, HERTFORDSHIRE.

M.230

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

M 233

PREFERRED BY THE MEDICAL PROFESSION FOR NEARLY A CENTURY

these essences rouse appetite and aid digestion

BRAND'S
ESSENCES
OF BEEF OR CHICKEN

Just on a hundred years ago Brand & Company first introduced their Meat Essences. From that time until now Brand's Essences of Beef or Chicken have achieved fame because of the exclusive process and hygienic conditions under which they are manufactured.

Scientific tests have proved that these Essences are assimilated by the digestive organs 40 minutes quicker than ordinary foods and without the formation of residue.

99 out of every 100 doctors recently interviewed recommend Brand's Essences of Beef or Chicken in cases of intestinal disturbances, in fevers, before and after operations, and particularly in all cases where the patient's recovery is hampered by anorexia.

Brand's Essences are the pure juices of the finest freshly killed English meats, extracted by an exclusive process with no other substance added. Samples will be sent on receipt of a professional card. Dept. F.25, Brand & Co., Ltd., Mayfair Works, Vauxhall, London, S.W.8

HORLICK'S MALTED MILK

A VALUABLE ADDITION to a diet at any time—especially so during the winter months. At this season of the year, the lack of stamina and diminished resistance to infection, so closely related to errors in nutrition, most conspicuously manifest themselves. It is therefore, all the more necessary that care should be taken to ensure that patients shall be given a diet which will satisfy their energy needs, lessen fatigue, prevent tissue waste and build up a reserve. HORLICK'S, a well-balanced food, with its easily digested protein, its readily assimilated fat and mixed carbohydrate—lactose, maltose and dextrin, and adequate vitamin content, promotes physical and mental fitness, increases resistance to infection and restores vitality. To combat Influenza, Pneumonia and other complaints so common in winter, HORLICK'S can be prescribed with confidence.

In Epidemics of

Colds Influenza Pneumonia

Physicians engaged in fighting prevailing epidemics continue to find in S.U.P. 36 a trusty weapon ready at hand and simple to use.

> "I have been very pleased with the effect of S.U.P. 36, and have come to rely upon a definite result—usually a drop of about 2° in the temperature within a few hours of the first dose, with marked increase in the comfort of the patient."

Such an addition to the armamentarium of a busy practitioner is of incalculable value.

Cumulative Evidence continues to testify to the value of

MEASLES
and
WHOOPING COUGH

The danger of these disorders is often in their far-reaching secondary effects.

During Convalescence from Measles there is a very special liability to tuberculosis invasion, many victims subsequently succumbing to Tuberculosis, Broncho-Pneumonia or Surgical Tuberculosis, and there is the same liability to Broncho-Pneumonia from Whooping Cough.

Virol is composed of Bone Marrow, Glycerine Extract of Red Bone Marrow, Malt Extract, Eggs, Lemon Syrup and Salts of Lime and Iron.
The Vitamins are present in Virol in its manufactured state.

Phagocytosis

The raising of the patient's powers of resistance is therefore important. Virol has been proved to increase the phagocytosic action of the leucocytes against the germs of Tuberculosis.

The convalescent stage calls for special reparative nutrition. Virol has a marked effect upon the conservation of the tissues, repairing the waste and restoring the equilibrium of a healthy metabolism.

VIROL

More than 3,000 Hospitals, Sanatoria, and Infant Clinics use Virol regularly.

COLLUMINA

A colloidal aluminium hydroxide

The therapeutic value of Collumina depends upon its ability to absorb the excess acidity of the stomach without giving rise to the unpleasant secondary reactions which often follow the administration of alkalies.

In addition, Collumina acts as a deodorant and is very effective in overcoming fetor of the breath.

Being mildly astringent and non-toxic, it is recommended as a mouth wash or gargle for the relief of congestion of the mucous lining of the mouth and pharynx.

Collumina is pleasantly flavoured and is supplied plain and also combined with bismuth for intestinal colic and diarrhoea.

Issued in 4oz., 8oz., and 16oz. bottles.

Prepared at
Evans' Biological Institute,
Higher Runcorn, Cheshire.

AMYL NITRITE "STERULES"

(MARTINDALE—Regtd. T.M. & Design)

IN BOXES OF 12 "STERULES"

Containing 1, 2, 3, 4, 5, 6, or 10 minims (0.05, 0.1, 0.2, 0.25, 0.3, 0.35, or 0.6 c.c. approx.), the usual dose being 3 minims (0.2 c.c.).

For relieving ANGINA PECTORIS, SPASMODIC ASTHMA, MIGRAINE, POST-PARTUM HAEMORRHAGE, HAEMOPTYSIS, to ward off EPILEPTIC ATTACKS, etc., and as an ANTIDOTE to CHLOROFORM. Largely employed in threatened FAINTING and COLLAPSE, and as a RESTORATIVE after GAS in DENTAL OPERATIONS.

Abstracts from the medical literature:

ANGINA PECTORIS: "The best remedy. To lower blood pressure has a more rapid action than any other drug, and is useful in cutting short the paroxysms of pain." —L., ii/05, 325; ii/06, 1335.
"Gave prompt relief in the more pronounced attacks." —B.M.J., ii/06, 304.
"In all spasmodic affections, such as angina pectoris, one of the best remedies."—B.M.J., i/09, 994.
"The nitrites are indispensable."—B.M.J., ii/09, 1122.
"The quickest means of relieving the acute pains." —L., ii/08, 1132.
"Fear of death entirely disappeared."—L., ii/09, 572.
"No drug can compare with Amyl Nitrite."—L., i/09, 240; L., ii/05, 812.

INTRATHORACIC ANEURISM: "For the acute anginal attacks Amyl Nitrite inhalation, followed by internal use of Nitroglycerin or Erythrol Nitrate, is generally efficacious."—L., i/13, 948.

ASTHMA: "In most cases the reduction in blood pressure relieves."—B.M.J., ii/11, 1327.

POST-PARTUM HAEMORRHAGE: "Immediately stopped; no further trouble followed."—B.M.J., ii/06, 1125.

HAEMOPTYSIS: "With few exceptions, promptly effective. Secures peace of mind to sufferers." —L., i/08, 130.
"Some convincing cases in which it saved life." —L., i/07, 939.
"Amyl Nitrite the drug par excellence; acts better the quicker it is used."—Edin. Med. Jl., 1904; L., ii/04, 522, 942, 1446; B.M.J.E., i/06, 79.
"In severe haemoptysis—rupture of an atheromatous pulmonary vessel—free use satisfactory."—B.M.J., i/06, 917.

SEA-SICKNESS: Very useful; inhalation repeated every 2 or 3 hours if necessary.

CHLOROFORM SYNCOPE: The quickest means of restoring the heart's action.

A Paper
ON
CLASSIFICATION OF BRAIN TUMOURS AND ITS PRACTICAL APPLICATION*

BY
WILDER PENFIELD, B.Sc.OXON., M.D.
MONTREAL

(*With Special Plate*)

I consider it a very great honour to be called upon to open this discussion, particularly as the president of the Section has himself played so distinguished a part in formulating our modern conception of the pathology of brain tumours. Further, it is peculiarly fitting that this meeting should take place in Winnipeg, for the important work on this subject that is being carried out by Professor Boyd of this city is known throughout the Empire. The topic was originally intended to be that of neurological surgery or of brain tumour. It may be permitted me, perhaps, to take exception to the implication that the two subjects are synonymous. Neurological surgery (or better, neuro-surgery) began, and should always continue, in my opinion, as an integral part of neurology; it was concerned at first largely with brain tumours. It has since expanded so rapidly, however, that the treatment of brain tumour now makes up a minor portion of the whole specialty. During the first twenty months of the existence of a department of neuro-surgery at McGill University there have been carried out by Dr. Cone and myself 250 major neuro-surgical operations (exclusive of 160 ventriculograms and encephalograms). Of these only 73 were for brain tumour. In the remaining group are included many equally interesting lesions.

Tumour classification based on histological similarities must serve to separate out groups of neoplasms whose biological behaviour is likewise similar, otherwise the classification is of little practical value and has only academic interest. This is not the place to undertake extensive histological description. I have attempted to do this elsewhere (1927). The following classification, based to a considerable extent on the work of others, has fulfilled in my experience the essential purpose of separating the more benign from the malignant gliomas. It makes neuro-surgery more discriminating, and serves as a basis for treatment, for prognosis, and for analysis. After outlining the groups I shall cite examples of individual cases chosen so as to illustrate the type of behaviour which we have learned to expect from the more common of these groups.

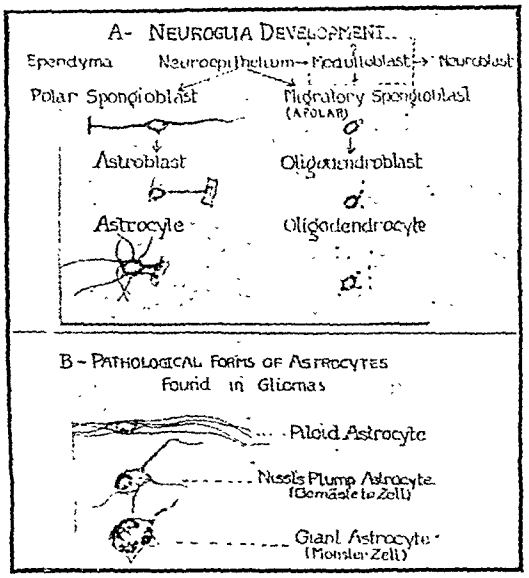

FIG. A.—Sketches of embryological and pathological forms of neuroglia which are commonly seen in gliomas. These are recognized by their morphology rather than by specific staining characteristics. Piloid astrocytes contain very long fibres, and appear within the brain where nerve fibres have been destroyed. Such cells rather than the astrocytes of the normal brain appear in astrocytomas. Nissl's plump cells, and also giant cells, are found in multiform spongioblastomas, where there is much focal vascular obliteration similar to that in areas of chronic vascular change within the brain.

The great majority of tumours of the brain may be taken up under two chief headings: (*a*) gliomas, which arise in the parenchyma and infiltrate nervous tissue, and (*b*) tumours of the sheaths of the nervous system, which are generally encapsulated and do not infiltrate nervous tissue. Because of their comparative rarity neither the locally malignant sarcomas of the meninges, nor the adenomas of the pituitary, nor the tumours of the cranio-pharyngeal pouch which appear about the sella turcica will be discussed here. Tumours of the pineal gland, although rare, must be considered, particularly when there is a hypothalamic or midbrain symptomatology. Metastatic tumours are not included. The haemangiomas of the cerebral cortex are of some importance, and the haemangiomatous cysts are of considerable moment, inasmuch as haemangiomatous nodules surround themselves by fluid, and thus form an intracerebral, or more often an intracerebellar, cyst, which yields gratifying results, provided the intracystic nodule be removed (Lindau, 1926, Cushing and Bailey, 1928, Sargent and Greenfield, 1929).

GLIOMAS

The term "glioma" was first employed by Virchow, who recognized that these tumours were composed of neuroglia cells. Numerous sporadic studies were made of gliomas, but the concentration of material was not sufficient for important work until Horsley opened up the field of neuro-surgery at Queen Square, and Tooth was there provided with 500 cases of brain tumour, over half of which were verified. Tooth (1913) did not subdivide the gliomas, but he observed that increase in size of cells corresponded with a high degree of malignancy. It is obvious that he was referring to the malignant multiform spongioblastomas which also contain Tooth's "glomerular multiplications of vessels." He described "annulation" (pseudo-rosettes), and pointed out that a large number of small undifferentiated cells signified malignancy. Here he doubtless referred to tumours since called medulloblastomas.

Roussy, Lhermitte, and Cornil made an effort to classify brain tumours (1924). They recognized astrocyte-containing tumours (astrocytomas), also ependymogliomas (ependymomas), as entities, both of which had been repeatedly described by earlier workers. They further isolated "polymorphous gliomas," which had been described roughly by Ribbert, and clearly by Globus and Strauss (1918 and 1923), under the name of spongioblastoma multiforme. The analysis of a large, well-organized group of tumours by Bailey and Cushing (1926), on the basis of the type cell of each form, has shown that not only can gliomas be subdivided by their histological appearance, but also that these subdivisions have distinctly different growth characteristics. If treatment is correct, the probable survival period of patients varies from a few months for those with multiform spongio-

* Read in opening a discussion in the Section of Mental Diseases and Neurology at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

blastomas to between two and twenty years for those with astrocytomas. Bailey and Cushing believed that generally the degree of histological differentiation of the tumours varied inversely with their malignancy, and that the more differentiated tumours were more benign, and the more embryonic tumours were more malignant. This is true to a limited extent, but it must be borne in mind that in addition to the type cell from which a tumour group gets its name, there may be present more and less differentiated cells as well. Thus in an astroblastoma there may be present numerous polar spongioblasts and also a few differentiated astrocytes.

The developmental and pathological cell types which are encountered in gliomas are roughly sketched in Figure A. They will be referred to under the headings of the tumour groups.

What we have found to be the most useful and simple classification of gliomas is as follows:

Gliomas	*Synonyms*
1. Neuro-epithelioma (Flexner)	Medullo-epithelioma and neuro-epithelioma of Bailey and Cushing.
2. Multiform spongioblastoma (Ribbert, Globus and Strauss)	Gliosarcoma (Borst); glioblastoma multiforme (Bailey and Cushing); polymorphous glioma (Roussy, Lhermitte, and Cornil).
3. Medulloblastoma (Bailey and Cushing)	Small round-cell glioma, glioma sarcomatodes (Borst). Pineoblastoma (Bailey and Cushing).
4. Oligodendroglioma (Bailey and Cushing)	
5. Polar spongioblastoma	Neurinoma centrale. Unipolar spongioblastoma (Bailey and Cushing).
6. Astroblastoma (Bailey and Cushing)	
7. Astrocytoma (Golgi)	Astrome (Lenhossek).
8. Ependymoma	Ependymoglioma; ependymo-epithelioma; ependymoma and ependymoblastoma of Bailey and Cushing.

1. *Neuro-epitheliomas* are encountered in the retina, the central nervous system, and even occasionally in the peripheral nerves, where they seem to arise from the anlage of the sheath of Schwann cells. They are characterized by the formation of neuro-epithelium (not ependyma), often in the shape of true rosettes. They contain numerous mitotic figures, and may even metastasize and erode the skull. They are usually, but not always, rapidly fatal. We know of one case which seemed to react favourably to *x*-ray treatment.

2. *Multiform spongioblastomas* are characterized by variety of cell form. There are usually small cells like apolar spongioblasts, and the presence of Nissl's plump astrocytes and giant cells is altogether characteristic (see Fig. A). However, other cells in the spongioblastic series may be present. Most characteristic of all, the blood vessels show curious glomeruloid out-buddings, and there are widely scattered focal necroses and often small cysts. These tumours are usually encountered in middle age and arise deep in the cerebral hemispheres. They are sometimes multiple, but practically never metastasize. They run a rapidly fatal course from the first symptom, usually lasting less than six months, occasionally two years. Operation on these cases is ordinarily followed by death in a few days from brain swelling unless "apparently total" extirpation is possible, in which case death may be postponed six months. These tumours are relatively frequent (30 per cent. of the gliomas in Bailey and Cushing's series) and cannot be considered hopeful subjects for surgical therapy.

As an example of multiform spongioblastoma treated by amputation of occipital lobe, the following case is given.

The patient, F. B., was a right-handed man, aged 50, who complained of headache for one year, alexia and aphasia for four weeks. On examination the patient was found to be somewhat confused. He was unable to read, although he understood almost everything that was said to him. There was a bilateral papilloedema and a partial homonomous defect in the right visual fields.

A left posterior osteoplastic craniotomy, under novocain anaesthesia, showed the dura to be under great pressure. No tumour presented itself on the surface, but the cortex was somewhat yellow, and an exploratory needle met with definite resistance at a depth of 2 cm. An incision was made through the cortex and a solid tumour encountered. It was seen to occupy the centre of the occipital lobe. The whole lobe was therefore amputated, no gross evidence of tumour being left behind (Fig. 1, Special Plate). The patient left the operating room in good condition. For the following ten days he was drowsy, showed a marked aphasia and a right-sided hemiplegia evidently associated with brain swelling. This cleared up and he returned home. During the next three or four months he was happy and quite free of symptoms. At the end of this time he began to have epileptic seizures, the aphasia and headaches returned, and he died about six months after operation, obviously from a recurrence of the tumour.

Most of these multiform spongioblastomas are too deeply situated in the hemispheres to permit such radical removal. Partial removals are usually followed by post-operative death.

3. *Medulloblastomas* are cellular tumours whose microscopic appearance is almost always the same. The cells contain rounded nuclei closely arranged and possess little cytoplasm. Although Bailey and Cushing called the type cell a *medulloblast (Schaper's indifferent cell)* because in certain rare instances it seemed to form neuroblasts, it would be better to consider that these tumours are made up of apolar (migratory) spongioblasts, which the type cell resembles. We have never been able to find neuroblasts in these tumours. There is a complex connective tissue stroma attached to the blood vessels. The cells frequently form ball-like clusters with hollow centres. Mitoses are moderately frequent, and the tumours infiltrate the brain, although a line of demarcation may often be grossly evident. They do not metastasize through the blood stream, but may on occasion invade the leptomeninges, to be disseminated through the spinal fluid. These tumours, which constitute 11 per cent. of Bailey and Cushing's series, are most often seen in the cerebellum, where they arise from the roof of the fourth ventricle, especially in children. They are less malignant than the foregoing group and are favourably influenced by radiotherapy, undergoing sclerosis with increase of stroma and destruction of the type cell.

The following case of extirpated medulloblastoma of the cerebellum illustrates the condition.

The patient was a boy, aged 12, who had complained of occasional vomiting for six months, occipital headaches for two months, diplopia and dimness of vision for six weeks, dizziness, ataxia, and drowsiness for four weeks. On physical examination the boy proved to have a moderate papilloedema, a weakness of the left external rectus muscle, an irregular nystagmus on gaze to the left, and symmetrically decreased reflexes and unsteadiness in standing and walking. Because of the fact that there were calcifications in each cerebral hemisphere seen in *x*-ray plates of the skull, a ventriculogram was done which showed a symmetrical dilatation of the lateral and third ventricles (Fig. 2, Special Plate). The calcification was seen clearly to be in the choroid plexus of each lateral ventricle and without pathological significance. A suboccipital craniotomy was carried out by my associate, Dr. Cone, under novocain anaesthesia. No tumour was seen when the cerebellum was exposed, but on separating the lateral lobes a greyish tumour was found which extended

into the fourth ventricle. The tumour was removed, apparently completely, together with some of the choroid plexus from the fourth ventricle. The patient made an uneventful recovery. All signs and symptoms disappeared. He has received several series of *x*-ray treatments, and during the eighteen months since operation the boy has carried on his school work and played hockey without evidence of recurrence.

Complete cure is possible, but we must anticipate recurrence within five years. If that happens, secondary removal will be undertaken.

4. *Oligodendrogliomas* are equally cellular neoplasms, but they are much more differentiated than medulloblastomas. Their type cell is not in reality oligodendroglia, but the more embryonic oligodendroblast (Fig. A). The cells are difficult to impregnate, but there may be pericellular haloes quite easy to recognize and resembling the haloes seen in acute swelling of oligodendrocytes in the brain. Small astrocytes and occasional differentiated oligodendrocytes (oligodendroglia) are present. Just as is the case with all the more differentiated gliomas the stroma is made up of blood vessels. The tumours grow very slowly. Mitoses are rare, and they often contain scattered calcification. They are found in the cerebral hemisphere, where they infiltrate the brain to such an extent that there may be no demarcation. Their consistency resembles that of cerebral tissue. These neoplasms are rare (3.5 per cent., Cushing and Bailey) and give favourable results after operation.

An oligodendroglioma treated by frontal lobe amputation will serve as an example.

The patient was a woman, aged 43, who gave a history of convulsive seizures at long intervals, beginning at the age of 19 years. During the previous four years the attacks had become more frequent. They began in the left arm. She complained of headaches, and later of vomiting, and some weakness of the left hand. For five years she had found administrative work difficult and eventually impossible, although clear in every other way. Physical examination showed that she had a bilateral papilloedema and very slight increase of deep reflexes on the left side. *X* rays showed calcification in the right frontal lobe (Fig. 3, Special Plate).

A large right frontal osteoplastic craniotomy was carried out under novocain anaesthesia. The presence of the tumour betrayed itself on the surface only by an increased vascularity. The pattern of the convolutions was maintained. On making an incision into the suspected area greyish-brown neoplasm was encountered. By use of galvanic stimulation the brain just posterior to the tumour was demonstrated not to be the motor gyrus. It was obvious in this case that the motor gyrus was pushed back to a point behind its usual situation in the cranial cavity. The amputation was therefore carried out through normal brain tissue posteriorly. After the removal it was discovered (alas!) that the neoplasm had passed across into the opposite hemisphere (Fig. 4, Special Plate). Removal of this portion was not attempted. The whole procedure was carried out under novocain anaesthesia, and although it was necessary to transfuse the patient three times on the operating table she left the operating room conscious and in fairly satisfactory condition.

Three weeks after operation she left the hospital feeling well, and in the nineteen months which have since elapsed she has been able to look after her large family better than at any time during the last five or ten years. There are now no signs or symptoms of the tumour, although the recent recurrence of a Jacksonian convulsion suggests that the tumour is growing again in spite of continued *x*-ray treatment. The complete absence of any immediate mental symptoms attributable to the removal of the right frontal lobe is obviously to be explained by the fact that other portions of the brain had taken over the function of this lobe during the very slow growth of the tumour. A secondary removal may have to be undertaken any time within the next ten years. In the meantime the patient is happy, and leading an eminently useful life as the mother of six children.

5. *Polar spongioblastomas* are composed of elongated cells whose tail-like cytoplasmic expansions may be mistaken for fibres unless the observer is on his guard. The cells are usually bi-polar or tri-polar (Fig. A), and occasionally unipolar or multipolar. Degeneration and cyst formation are frequent and mitosis is rare. The cells may be found attached to blood vessels and may differentiate into astroblasts. Confusion may arise between this tumour and astrocytoma, but this may be avoided if a stain for neuroglia fibres be used. Such fibres are not found in polar spongioblastomas. Further, without differential stains, these tumours bear a resemblance to perineurial fibroblastomas (see below), although the latter never infiltrate the brain. Polar spongioblastomas, which must be clearly distinguished from multiform spongioblastomas, are comparatively rare. They are slow-growing and are most frequently encountered in the cerebellum.

The following example illustrates polar spongioblastoma of the cerebellum removed by suction.

The patient was a girl, aged 16, who gave the following history. Thirteen months before admission she began to notice diplopia, particularly on looking down. Shortly after this, headaches and occasional vomiting developed, followed by mists before the eyes. Physical examination showed unsteadiness in walking and in standing with the feet together. She had a papilloedema and there was a coarse nystagmus on gaze to the left, with a fine nystagmus on gaze to the right. The deep reflexes were symmetrical but somewhat difficult to elicit.

A suboccipital craniotomy was carried out on January 29th, 1929. The pressure was very high. The tumour was felt with an exploratory needle at a depth of 4 to 5 cm. beneath the right cerebellar hemisphere. A profuse arterial haemorrhage followed the exploration with the needle, and the patient's condition became so critical that it seemed best to close the wound, leaving the dura open A transfusion was given. Following this operation the patient's condition became very rapidly worse. She was unable to feed herself because of ataxia. Her speech became so thick that she could not be understood. A second operation was carried out eight days after the first. The wound was reopened, and this time the cerebellum was split in the midline. At a depth of about 4 cm. from the surface of the vermis, and high up beneath the tentorium (Fig. 5, Special Plate), a semi-solid tumour was encountered. One large piece was removed *en bloc* and the rest of the neoplasm was removed by suction. The next day the patient was much less drowsy, speech was improved and was intelligible. The following week the ataxia of the limbs gradually improved. However, on leaving the hospital, the patient was able to walk only with assistance because of her ataxia, most marked in the right leg. Her speech was still cerebellar in type.

During the nineteen months which have elapsed since the second operation, the patient has steadily improved. At the end of the year her speech was almost normal, and she was able to play the piano again. There is now practically no trace of her old ataxia. She can play the violin, and finds that bowing is her only difficulty.

This case illustrates the difference between the conservative and the radical treatment of brain tumours. The remarkable recovery was of course only possible because the tumour was a polar spongioblastoma and not a more malignant type. Had the patient been left as she was following the first operation, however, when it was decided that the tumour was too deep to risk removal, the result would almost certainly have been death in a pitiable state. After the second operation, with the tumour out she progressively came back to health. Had the tumour been removed at the first operation, as originally intended, the patient would have had none of the symptoms of increased ataxia and pressure, which were doubtless due to oedema in the vicinity of the tumour.

6. *Astroblastomas* present a quite characteristic arrangement of cells about blood vessels and connective tissue

septa. The nuclei leave a zone free about the vessel. If successfully stained with silver (most easily done with a modification of Hortega's microglia method) they are found to have long vascular foot processes like astroblasts in newborn mammals (Fig. A). The processes may be faintly seen by Mallory's phosphotungstic acid stain and even by haematoxylin and eosin. There may be numerous cells not applied to vessels which are morphologically polar spongioblasts as one might expect from a knowledge of the development. These tumours are moderately slow-growing, but may contain mitotic figures. In Cushing's cases they appeared in adults and were all found in the cerebral hemispheres. In our own clinic there have been four of these tumours, three of them in the cerebellum, and all in children. One recurred a year after radical removal. Lack of space does not permit illustration here.

7. *Astrocytomas* were subdivided by Bailey and Cushing into fibrous and protoplasmic types. I have never encountered such a tumour without neuroglia fibres, and can see no object in such a multiplication of names. It should be recognized at once that these tumours rarely contain cells that resemble astrocytes of the nervous system. On the contrary, the type cell is what we have called (1930) the piloid astrocyte (Fig. A), which appears in the brain in old scars and in columnar sclerosis. In other words, the piloid astrocyte appears in the central nervous system where nerve fibres are absent, and it is to be expected therefore in a neoplasm. The cells often contain elongated nuclei, and appropriate stains disclose neuroglia fibres. Foot-plates can always be found. Occasionally giant cells appear as degenerative forms. Mitoses are rare, and the formation of large cysts is frequent. These are the most benign of all gliomas, and, fortunately, as shown in Bailey and Cushing's series, they represent the most numerous group (40 per cent.). They may appear in cerebrum or cerebellum, and splendid results follow removal.

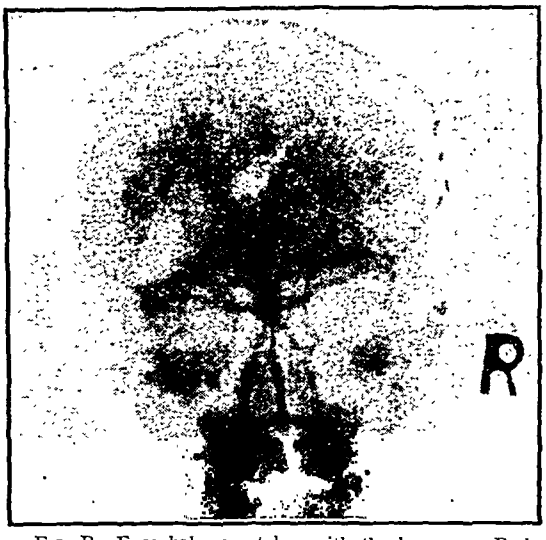

FIG. B.—Encephalogram taken with the brow up. Both anterior horns are filled and displaced towards the left. The silver clips indicate the field of Dr. Cushing's previous operation.

The case described below is one of astrocytoma of the cerebrum treated by operation and re-operation.

The patient was a little boy, who, at the age of 8, began to complain of weakness in the left arm and leg. He also had attacks of Jacksonian epilepsy confined to the left side, and followed on one occasion by hemiplegia. He was operated upon by Dr. Cushing at that time (1926), and an astrocytoma of the right parietal lobe was removed. After operation he was free of all symptoms for a year, at which time he began to have epileptic seizures. The boy continued to be well and to go to school. The attacks gradually increased in frequency until he entered our clinic under the care of my associate, Dr. Cone, three years after his operation. On physical examination his optic discs were normal. There was a definite increase in the deep reflexes of the left side and weakness of the left abdominal reflex; plantar response on the left was extensor.

An encephalogram was done in order to determine whether or not there had been a large recurrence. The left lateral ventricle filled, but there was no filling of the body, posterior or inferior horns of the right lateral ventricle. The right anterior horn filled, but was displaced across toward the left (Fig. B). Dr. Cone reopened the osteoplastic flap and found a very large cyst in the parieto-temporal region. At the base of the cyst, and extending into it, was a solid tumour. The roof of the cyst was completely removed, and it seemed to be made up of very much thinned-out cerebral tissue, and the tumour at the base was extirpated (Fig. 6, Special Plate). Electrical stimulation was used to prevent removal of the motor area. The operation was carried out under novocain anaesthesia. Following the operation there was hemiplegia chiefly involving the left arm. This has gradually cleared up, so that there remains only a slight degree of weakness in the left leg. The boy is doing well in school, and during the six months which have elapsed since operation has had no further epileptic seizures.

This patient was chosen to illustrate the astrocytoma group, as he shows the importance, in the production of symptomatology, of the formation of cysts by these tumours. The case also illustrates the possibility of successful multiple operations in these conditions.

8. *Ependymomas* are easily recognizable, inasmuch as the pathognomonic histological characteristic is the production of ependyma either in rings or in epithelial sheets. Cilia may often be stained, and, at the base of the cilia, centrioles or blepharoplasten. Between the areas of epithelial structure polar spongioblasts may be numerous, and cells may differentiate into astrocytes. I have never seen mitotic figures in these tumours. They grow slowly and are often well circumscribed. It is frequently difficult to remove them, because of their deep-lying situation. The midline of the cerebellum is a favourite site of origin. They are comparatively more frequent in the spinal cord than in the brain.

B. TUMOURS OF THE NERVOUS SHEATH

Generally speaking the encapsulated tumours have been better recognized than the gliomas, although the cytological interpretations have been curiously varied. This has been discussed elsewhere (1927) and need not be reviewed at present. In general, the gliomas arising within the brain do not pass outward through the pia mater, and, conversely, the tumours of the meninges and nerve sheaths, arising without, never pass inward through the pia mater.

The tumours of the sheaths are best classified as follows:

Sheath Tumours	*Synonyms*
1. Meningeal fibroblastoma	Dural endothelioma, psammoma, arachnoidal fibroblastoma (Mallory), meningioma (Cushing).
2. Perineurial fibroblastoma (Mallory)	Solitary neurofibroma, neurinoma (Verocay), cerebellopontile angle tumour, peripheral glioma, etc.
3. Neurofibroma of von Recklinghausen's disease.	

1. *Meningeal fibroblastomas* are attached to, and vascularized by, the dura, usually arising in the arachnoidal cell tufts, which they resemble histologically. The lepto-

meninges seem to be quite obviously mesodermal (Weed, 1930) in spite of occasional efforts to establish for them an ectodermal origin, and the type cell of these tumours forms fibroglia and collagen, distinguishing characteristics of fibroblasts. The histological structure most characteristic of these tumours is whorl formation as in the arachnoidal tufts. Meningeal fibroblastomas may invade the skull, causing bone thickening, but they do not enter the brain. They grow slowly and may occur after many years if not completely removed, but are not malignant as the meningeal sarcomas may be. It may be pointed out that the term meningioma does not differentiate these two tumours.

The following case is an example of meningeal fibroblastoma localizable only by ventriculography.

The patient was a right-handed woman, aged 52, who had complained for four years of gradually increasing childishness and memory defect, with occasional involuntary micturition. For three years there had been motor aphasia of varying degree, and for two years progressive weakness of the left side. No headache and no vomiting had occurred.

On examination the optic discs were normal. There was evidence of a lesion to the pyramidal tract arising in the right hemisphere—aphasia and disorientation. A ventriculogram showed the anterior portions of both lateral ventricles pushed from the left to the right (Fig. 7, Special Plate).

A left osteoplastic craniotomy was performed, and a meningeal fibroblastoma removed from the posterior portion of the left frontal lobe. The neoplasm had infiltrated the overlying bone (Fig. 8, Special Plate). The infiltrated area of bone was excised as well as the attached dura, and a transplant of fascia from the thigh was made to close the dural defect.

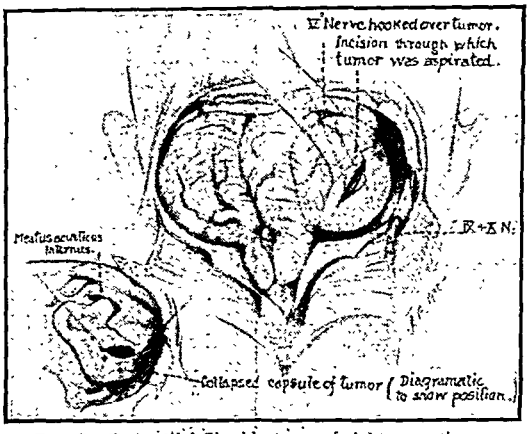

FIG. C.—Perineurial fibroblastoma of right acoustic nerve, much schematized to show the relationship of the tumour to the cranial nerves.

The only explanation of involvement of the pyramidal tract of the opposite side would seem to be that this tumour was so placed as to press the peduncle of the opposite side against the anterior attachment of the tentorium, a phenomenon which we have seen give rise to contralateral signs in another similar case. Following operation the patient has made a gradual but complete recovery, and is, of course, perfectly well now, sixteen months after operation. The bilateral, apparently diffuse, signs which this patient presented, and the absence of any evidence of increased intracranial pressure, rendered a positive pre-operative diagnosis impossible without ventriculography. It is in such cases that ventriculography is of the greatest value. Had the lesion proved to be on a vascular basis the injection of air should not have been detrimental.

2. *Perineurial fibroblastomas* arise from the connective tissue sheaths of nerves and particularly of nerve roots. As is well known, they most frequently arise from the sheath of the root of the eighth cranial nerve. Histologically the nuclei tend to form characteristic palisades. Silver staining reveals long, parallel, wire-like fibres similar to the reticulin (a form of collagen) in the perineurium and endoneurium of nerve fibres. These neoplasms do not metastasize, but frequently degenerate and become necrotic at the centre. They do *not* yield to *x*-ray treatment like gliomas.

A complete removal of perineurial fibroblastoma of the acoustic nerve was done on a woman, aged 35, who had complained of tinnitus aurium for three years, unsteadiness, headache, and failing vision for two years, and dizziness for one year. On examination she was found to have papilloedema, to be totally blind in one eye, and partially in the other. There was nystagmus, decreased corneal reflex on the right, and partial nerve deafness on the right.

A suboccipital craniotomy was carried out, the tumour encountered in the right cerebello-pontile angle (Fig. C), and the soft centre curetted out. The capsule was then carefully removed, and the internal auditory meatus laid open with a chisel and curetted for tumour remnants. After operation the right seventh nerve was paralysed, but the fifth, ninth, and tenth nerves were intact. The second operation was carried out three weeks later, and a hypoglossal to facial nerve anastomosis performed. At present, five months after operation, the vision is improved and headaches have gone. She still complains of dizziness and ataxia of right extremities.

If a partial removal be done in these cases the post-operative course is much smoother, the seventh nerve is not injured, and the fifth is not endangered, but recurrence within a few years is inevitable.

3. *Neurofibromas* may appear on any nerves, of course, and are multiple. Nerve fibres are found histologically running through those tumours, while in perineurial fibroblastomas they pass around the capsule. In addition to the presence of nerve fibres in the tumour substance the whole histological pattern of neurofibromas is more mixed than that of perineurial fibroblastomas, although there are usually certain microscopic fields which give a similar appearance. The treatment depends upon their location. They may on occasion undergo malignant change into sarcoma.

CONCLUSION

In conclusion I must apologize for reviewing many things with which, no doubt, many are already familiar. This is inevitable, perhaps, when the topic covers so large a subject. Brain tumour classification and the practical application of surgery to this otherwise fatal malady is a work to which a large number of workers have contributed varying talents. The classification outlined above has formed, in our experience, a satisfactory basis for analysis. With certain alterations and considerable simplification the portion that has to do with gliomas is derived from the outline of Bailey and Cushing (1926). Except for simplification the whole classification corresponds with the outline adopted by the committee on terminology of the American Neurological Association, an outline which it was originally my task to prepare for the committee.

It must be urged, finally, that it is necessary for the neuro-surgeon himself to understand as nearly as possible the characteristics of the lesion he would combat. Technical excellence is not enough. Clinical judgement and therapeutic insight must be based upon discriminating histological study. As far as names are concerned, this classification is, of course, only one of a number of possible ones, but it withstands the test of practical clinical application (see also Cutler, Moritz, and Zollinger, 1929) and is the result of careful cytological and embryological study. It is of the utmost importance for those of us who work in this field to ignore minor differences

of opinion as to priority and the niceties of terminology, and to unite in a combined study of the problems before us, using a common classification for a starting point.

(From the Henry Phipps Institute, University of Pennsylvania)

(*With Special Plate*)

In treating the important topic of tuberculosis in children, my point of view is necessarily much influenced by an interest, dominant during the past seven years, in the pathogenesis of the disease and in the course of its evolution. At the Henry Phipps Institute the incidence and progress of infections have been studied in family groups. No hospital beds are in the dispensary, nor have we access to a sufficient number of beds elsewhere to afford prompt hospitalization and sufficiently long treatment to many of our cases. This advantage, common to many communities, is peculiarly inimical to attempts to stamp out the beginning infiltrations of children. It is difficult at best to persuade an adolescent or the parents of a younger child, when symptoms are trivial or absent, that rest in bed is necessary to avert a serious illness. Delayed admission to an institution known to be crowded does not strengthen the appeal of an enforced rest. However, serial *x*-ray observations and correlated attempts to regulate the lives of children who defer or refuse institutional care are sometimes followed by retrogression of their lesions, and always place one in a stronger position to urge absolute rest in bed at the onset of definite symptoms. Furthermore, one is in a position to record the fluctuations of a lesion and to learn how extensive may be the damage capable of retrogression and healing without excessive surgery, essential and life-saving though surgery is in very many cases. Although one's observations are restricted through concentration on certain problems, it is clearly impossible within a brief space to do more than outline a few aspects of tuberculosis in children, and to indicate means of detecting, preventing, and treating its protean appearances in the diverse phases of infancy, school age, and adolescence. It is only by discussion from many angles and by free exchange of the fruits of experience and controlled observation, that we may hope for "new methods of approach to a subject which still defies exact comprehension and as to which there is still so little unanimity in the minds of investigators."[1] The interaction of seed and soil,[2] of infecting micro-organisms and host, produces a baffling and complex disease. In its development and manifestations, the type of tubercle bacillus, the size, number, and spacing of the "doses" on the one hand, and on the other the portal of entry and the race,[3,4] age,[5] sex, and environment of the infected person, are leading factors. The bovine sources of contagion will not be referred to in this brief consideration. For those interested in pulmonary tuberculosis, in its pathogenesis, epidemiology and clinical manifestations, the duration and intensity of infection or contagion,[6] and race and age, are perhaps the dominant considerations.

"The available amount of energy and money which can be applied to the extermination of tuberculosis is not unlimited, and so much of it as is spent on measures which are less likely to yield results than others must be considered to some extent to be wasted."[7] Newsholme's warning is not less significant to-day in view of the enormous economic waste of current methods. When the patient is ill enough to seek the physician the disease is usually so far advanced that months, even years, of treatment are a mere palliative. If the patient is retained in hospital, expensive facilities and care are required to secure a clinical recovery, which must be followed by years of careful rehabilitation; if he has a shorter inadequate hospital stay, he goes home a well of contagion, to infect those living in his environment. There is a tendency among those faced with these difficulties to find in the declining death rate a reassurance that only too often results in paralysis of effort. But the fall in mortality, the nature of which has been well defined by Cobbett,[8] should not be so interpreted that activities languish and fail to be progressively directed against the most destructive phases of tuberculosis. Moreover, amazing though the fall in the death rate is, tuberculosis mortality in England and Wales in infants under 1 year was 109 per 100,000 births in 1927,[8] and in the age periods from 5 to 10 and from 10 to 15 years, although the death rate from all causes was low, tuberculosis accounted respectively for 14.43 per cent. and 22.53 per cent. of the deaths. But it is in adolescence and in early adult life that we find the peak of tuberculosis mortality, and here, too, we find in tuberculosis economically the most destructive and wasteful of diseases. It cripples more or less permanently or destroys at the beginning of usefulness the carefully trained economic unit representing years of education and the summation of family hopes. It strikes the patient down sometimes rapidly, more often in a series of relapsing illnesses. Further, during the quiescent intervals, the patient may pass on the infection to the next generation. Moreover, there is evidence that, at least in some large cities, there is not a diminution in the percentage of the population infected corresponding to the diminished total tuberculosis mortality.[9] The tuberculin reaction shows that infection with the tubercle bacillus is still as nearly universal in city dwellers of European stock as it was twenty-one years ago.[10] It is impossible to ascertain how many of these infections would flare up under conditions of unusual strain or privation, as is suggested by the steep ascent of the tuberculosis mortality curves[11,12,13] in civil popula-

* Read in opening a discussion in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

tions during war. In normal circumstances, many latent infections escape attention because good living conditions constitute an undesigned but adequate prophylaxis for this group. That other large group of cases which even under normal conditions develop into demonstrable latent infiltrations is the chief object of the search and attack in tuberculosis control.

HOUSEHOLD CONTAGION FOCUS OF STUDY, PREVENTION, AND TREATMENT IN TUBERCULOSIS

In seeking the most practical attack on infantile and adolescent mortality (and knowing that the combating of the latter is often grounded in the lesion, latent or clinical, of adolescence), a most rewarding procedure is to be found in the serial examination of those living in household contact with sputum-positive tuberculosis. We have used the term "latent" somewhat arbitrarily, but with a meaning that is appropriate to case-finding methods, to designate the pre-clinical stage of a tuberculous pulmonary infiltration, when it is demonstrable by *x*-ray examination but does not yet manifest itself clinically by symptoms or signs perceptible to the patient or by the usual methods of classical physical examination. In a report[8] based on observations extending over slightly more than two years, it was shown that among a group of children of whom either the father or mother had positive sputum, about 9 per cent. showed clinical tuberculosis, about 2 per cent. well-defined latent pulmonary infiltrations, and about 20 per cent. calcifications of the tracheo-bronchial lymph nodes. In these children the number of pulmonary lesions has increased during four years of subsequent observation. Among a control group of children living in households no member of which had a history of pulmonary tuberculosis, there was no instance of clinical tuberculosis, and only about 4 per cent. showed calcifications of the tracheo-bronchial nodes. Among the first 102 families reported, 34 had one or the other parent sputum-positive, 33 had no member with tuberculosis, and in 7, one of the children (the eldest in five instances) had open tuberculosis. Although it is possible that in these seven cases the source of infection of the patient was extrafamilial, we were not able to examine the parents for pulmonary infiltration or to obtain adequate evidence of the cause of death of parents not living.

The first examination of contacts of a freshly reported case of open tuberculosis often discovers remarkably little evidence[14] of severe infections which reward supervision. Sometimes, indeed, even the tuberculin reactions may be slight or absent in certain children. If the tuberculin test is made intracutaneously with measured quantities of a standardized tuberculin,[15] and reactions occur only with the larger quantities (0.1 mg. and 1.0 mg. O.T.), strong evidence has been obtained that the exposure to positive sputum is both recent and short, and, in substantiation of this, the *x*-ray picture may show in the source of contagion a lesion that is evidently wholly soft and recent, or may present evidence of an old lesion with recent exacerbation. If, in addition, roentgenograms of the children show no evidences of long-standing exposure—such as tracheo-bronchial calcifications, etc.—the bacillary content of some twenty specimens of sputum as measured roughly by the Gaffky count, and the frequency of expectoration, will give the nearest approximation to a measure of the intensity of exposure in such cases. If the sputum shows few bacilli and the cough is infrequent, it is probable that the sum of infection has not been severe. Nevertheless, because of the uncertainty of all these measures of contagion, the tuberculin test should be repeated in some four to six months, and neither satisfactory hygienic living conditions nor serial *x*-ray supervision should be neglected. A family history is appended:

Father, aged 31, ill five weeks with cough, sputum, and haemorrhage; onset acute, of the type resembling grippe. *X* rays show a few old strands in the extreme apex, right and left, and in the right upper lobe flocculent spots becoming confluent to consolidate for some four centimetres beside the interlobar fissure in the axilla only. Twelve specimens of sputum negative, one positive, Gaffky IV. Patient hospitalized fourteen weeks after the onset of symptoms; died five months later of acute tuberculosis. Mother, aged 27, showed a small tracheo-bronchial calcification, but no pulmonary infiltration. Tuberculin positive to 0.1 mg. O.T. Santo, aged 8 years 7 months, showed a large pulmonary calcified nodule and large tracheo-bronchial calcifications. Tuberculin positive to 0.1 mg. O.T. John, aged 7 years 2 months, had a negative *x*-ray, and was negative to 1.0 mg. O.T. Carmella, aged 5 years 4 months, had a negative *x*-ray, and was negative to 1.0 mg. O.T.

Here the acute onset and the soft mottling and consolidation in the father and the negative tuberculin reactions of the younger children, one of pre-school age, suggest exposure of short duration. The relative infrequency of positive sputum indicates no great intensity of exposure. Possibly the tracheo-bronchial calcification and weak tuberculin reaction of the oldest child and the few old strands seen in the father's apices may, taken together, be interpreted as evidence that during the infancy of the eldest child the father had a slight lesion, which became arrested before the second child was born. Careful inquiry failed to discover that anyone else had lived with the family. That this family was not heavily infected during fourteen weeks' contact with the father is shown by a tuberculin reaction in the youngest child persistently negative annually for three subsequent years and by the occurrence in the second child of merely weak reactions to the highest doses (0.1 and 1 mg. O.T.) during the same period.

The immediate problem of supervision is, of course, the severity and length of infection to which any infants in the household have been exposed. In an infant, even a weak tuberculin reaction may signalize a dangerous infection. There is evidence[5] that even young infants may recover from lesions resulting from transitory severe exposure or slight exposure lasting several weeks. But in all cases there is grave danger that even a small lesion, whether of the lung or of one or several tracheo-bronchial lymph nodes, may progress or that metastasis to other areas, in particular the meninges, may occur. Therefore every precaution should be taken to prevent reinfection and to maintain the infant in the best possible living conditions, preferably in its mother's care unless she is the source of infection, and to ensure that the mother has time and means to care for it properly. The importance of preventing reinfection or superinfection is to-day probably generally recognized. But perhaps it is not so generally understood how the attachment to the infant of the source of infection, whether parent, grandparent, aunt, or uncle, will often result in an interruption of the patient's isolation from the baby and all that concerns it. Aseptic technique and clear appreciation of possible modes of transmission of infectious material come hard even to some physicians. In the absence of exact knowledge of the chances of infection—for example, by dry dust and by contamination of food and utensils and toys—merely to require that the patient with the open lesion shall not handle the baby is to take an indefensible risk with the infant's life. Although a positive tuberculin reaction in an infant is not conclusive evidence of immediate contact, it is sufficient to warrant the institution of every measure to ensure the prevention of further infection, including *x*-ray examination of all persons who have been in its environment.

At the other extreme is the result of the first examination of the contacts, typically father or mother, of a patient. One may have coughed and expectorated for years, with sputum presenting many bacilli in most specimens, and an *x*-ray film showing an old lesion, partly strand-like, with one or many spherical or multilocular smooth-walled cavities. There may be a history of a baby recently dead of meningitis. Of the younger children, half may show calcified tracheo-bronchial nodes, and of those past or at puberty usually one or more will show an infiltration of the upper third of the lung field, with or without symptoms and classical physical signs. The tuberculin reactions vary in intensity, but all, or all but one or two, react to 0.01 mg. O.T. The following cases are illustrative.

CASE I

Father, aged 39, sputum-positive, with symptoms extending back some seven years and an old strand-like lesion, largely excavated. Mother, aged 41, had no pulmonary lesion. Her tuberculin reaction was positive to 0.01 mg. O.T. At the first visit all eight children had positive reactions to 0.01 mg. O.T. A child 2½ years old had recently died of tuberculous meningitis. *X* rays showed that the three oldest children, aged 17, 16, and 15 years, had latent apical infiltrations, the third with associated tracheo-bronchial calcification suggesting, in conformity with observations in our studies of contagion, that her first infection was of intrafamilial origin. (The significance of calcification of these lymph nodes has been fully discussed elsewhere.[5]) Within three years from the first examination the oldest child, refusing rest in bed, became far advanced. The apical lesion of the next child at first advanced, but was improved by sanatorium care, unfortunately ambulant. The apical lesion of the third child (Figs. 1 and 2, Special Plate) progressed, despite a gain in weight, during ambulant sanatorium care. Another child in whom a fresh apical infiltration developed, with rapid spread, has improved remarkably with complete rest in bed (Figs. 27, 28, and 29 of Reference 5).

CASE II

The father of another family refused examination. The mother died of tuberculosis in 1918. The oldest child, a girl, died, also of tuberculosis, in 1921. The next, a girl aged 20, our first patient from this family, had a far advanced lesion with tracheo-bronchial calcification. The next child, a sister aged 17, had a latent apical lesion. The remaining three children, aged 15, 13, and 12, all showed tracheo-bronchial calcifications. The tuberculin reactions were all positive to 0.01 mg. O.T. Within one year from the beginning of our supervision the youngest child developed a severe infiltration, which has yielded to complete bed rest. (Figs. 3 and 4, Special Plate, and Figs. 16, 17, and 17A of Reference 5.)

These few diverse instances indicate at once how various and how logical may be the results of the first examination of contacts. The children of each household present evidences of infection that are, broadly speaking, reflections of the history and of the anatomical extent and condition of the lesion of the source of contagion. The correlation is clearer when a parent is the patient and the household has not at one time or another contained brothers, sisters, father, or mother of the patient—that is, when other and earlier sources of infection may be ruled out. In nearly all households, whatever the source of infection, the danger is immediate for children under 2 years, somewhat less urgent but more protracted for adolescents, and for children between these ages real, but for the most part deferred until puberty. In short, in children, as Newsholme[7] showed to be the case in adults, the latent period between the cessation of exposure and the onset of a clinically manifest lesion is often a matter of years.

An eldest daughter, all members of whose household had been serially examined (Fig. 11 of Reference 6), first showed an apical infiltration four and a half years after her father's death. Again, a boy, whose sputum-positive mother died in his sixth year, first showed symptoms in his fourteenth year. In this somewhat unusual case there is no evidence of other intrafamilial contact. Strong evidence that there was none is found in the negative tuberculin reactions of three younger brothers, who were aged 9, 7, and 5, within less than six months before the appearance of a positive sputum in this patient. No extrafamilial contact, always a possibility to be considered, could be traced.

It is not uncommon for children past puberty first to present infiltrations from the second to the fourth year after the cessation of contact. Jessel[16] found three and a half years the average interval. I have not found that annual *x*-ray examinations after contact has ceased could be dispensed with during a period covered by seven years' supervision of contact children. Supervision should be closer and more prolonged the nearer the period of contact to the years of adolescence. Known contagion, centring about a diagnosed case of sputum-positive tuberculosis, is the most economic starting point for discovering pulmonary tuberculosis in its most tractable phase. *X*-ray examination of school children[9 17] selected by the tuberculin reaction and the routine examination of young adults seeking employment[18] stand perhaps next in order of demonstrable value. *X*-ray examination of all school children, though more laborious and expensive, has the added advantage that it will reveal many chronic non-tuberculous pulmonary infiltrations, which, undetected and untreated, are productive of serious invalidism. Furthermore, adequate films will pick up indications, in heart size and shape and in pulmonary markings, of many cardiac lesions needing supervision that would nevertheless be overlooked by routine physical examination.

X RAYS IN DIAGNOSIS, SUPERVISION, AND CLINICAL INVESTIGATION

In a general way the importance of the *x* rays in the examination of the lungs is recognized. It is less generally known or admitted that they can afford basic information about the state and possibilities of a lesion, information that is subject to modification by evidence such as elevated temperature and various abnormal blood pictures, but is nevertheless in itself sufficient warrant for the institution and continuance of treatment in the absence of corroborative accessory findings. Ignored, the *x*-ray evidence will sooner or later receive disastrous amplification in signs, symptoms, and laboratory tests.

In earlier papers[19 20 5] histories are cited and lesions recorded, particularly in Figures 5, 14, 16, and 17, and 24 to 35 of Reference 5, illustrating how rapidly, how extensively, and for how prolonged a time tuberculous infiltrations can invade the lung substance and even destroy it while remaining latent in the sense defined above (Figs. 1 and 2, Special Plate). More recently, comparative studies, as yet unpublished, have shown that, although the blood picture[21 22 23 24] or the sedimentation test, or both, when repeated at relatively short intervals, rarely fail to reflect definitely progressive infiltration, both may be normal at a time when the *x* ray records a lesion the softness of which indicates an instability subsequently verified by spread. We should be most unwilling to dispense with the aid of either of these valuable indications of activity, properly defined. We hope that through extended comparative studies, subjected to continued analysis, they may throw further light on the course, particularly, of latent lesions, and furnish more certain criteria on which to base their care. But we do not yet know in what relation to place the evidence afforded by each of them in its various degrees of positiveness, and it is essential to evaluate all evidence carefully in dealing with a disease at once so insidious and so volcanic as tuberculosis. Having found that the

x-ray evidence may be alone decisive, we feel that in all cases, at least for the present, the anatomical extent, site, and condition, or softness, of the lesion as revealed by the *x* ray should be the major consideration, emphasized by these important but accessory tests when positive. This distinction should, above all, be insisted upon during the retrogression of infiltration, when only the *x* ray may reveal the extent of the lesion and lack of delimitation, denoting capacity for violent resurgence.

Economically, the greatest waste in the recognition and supervision of tuberculosis arises probably from the failure to institute promptly, and to continue, treatment for the lesions of children, particularly adolescents, until they show, by serial *x*-ray examinations, clear evidence of strand-like anatomical stability. To discharge adolescent children, symptom-free for a few weeks, without such results, is a cat-and-mouse form of treatment, building up hope over months, to destroy it over weeks or months or years. Nothing is more futile and visionary than to lavish attention and costly infirmary beds only upon the clinically manifest activity of so insidious a disease. Inexpensive accommodation can provide adequately for much of the stabilizing period of anatomical arrest if medical supervision is equipped with good *x*-ray and laboratory facilities, and informed by experience with tuberculosis and the tuberculous. Unquestionably, if there is evidence by *x* ray, sedimentation test, or differential count that a lesion is increasing, the patient should be returned to an infirmary bed. Infirmary beds should likewise be sufficient in number to permit alternating periods of complete rest in bed and of varying degrees of freedom for those whose lesions are only moderately well delimited and sluggish, showing little progress to stable strand-formation, despite, perhaps, negative blood tests. No doubt there will still be found those who, objecting that to give such a place to the skiagram is to allow it to define activity and so to determine treatment, will boggle at such an idea, largely because of the association of activity with venerated definitions. But definitions that are time-honoured may come to be time-worn. The value of any conception or definition of activity must depend on the accuracy with which it points to the course and potentialities of the morbid process. Before the development of dependable *x*-ray methods and the correlation of skiagraphic appearances in the living with those of excised material subsequently sectioned, certain physical signs, in particular rales, formed for many physicians the most dependable evidence of active tuberculosis. Physical signs had to be discarded as the index of activity because, on the one hand, they usually lag far behind the initial invasion and the development of fresh infiltrations, and, on the other hand, they may persist for years over anatomically stable and functionally cured lesions. Elevation of temperature and of pulse, the signs currently accepted as evidence of activity, are significant only in that they usually indicate an acceleration, intensification, or extension of the existing lesion. Like rales and symptoms, they neither coincide with the onset nor, by their disappearance, signalize the cessation of progressive infiltration or excavation. Alike in the latent or pre-clinical phase of pulmonary tuberculosis and during clinical disease, widespread extension and even excavations are commonly recorded, particularly in children, without changes in temperature and pulse. These are usually late and essentially secondary effects of the morbid process. When present they occur with no definite, much less proportionate, relation to the intensity and extent of the underlying infiltration, the means by which tuberculosis destroys lung and eventually life. Attempts to link these signs directly with phases of allergy, immunity, or lack of immunity, or with the so-called exudative stage of tuberculosis in children will receive scant support if closely spaced serial films are made of symptomless contacts (Figs. 1, 2, 3, and 4, Special Plate). (See also Figs. 5, 14, 16, 17, 17A, 20, 24, 27, 28, 30, and 31 of Reference 5.)

A pulmonary infiltration sufficient in extent to cause fever, or other signs and symptoms, rarely, if ever, escapes ready recognition by an adequate roentgenogram interpreted with regard to the anatomy of the chest, the pathology of tuberculosis, and the properties of the *x* rays.[5 25] In children and adolescents particularly, tuberculosis characteristically causes extensive damage with no febrile disturbance, or with such transient and trivial disturbances as commonly occur in healthy children. A conception of activity in which emphasis is transferred from the direct anatomical evidence presented in the *x*-ray film to such secondary haphazard effects, has lost the essential protection it can give the patient, and will allow negative evidence to camouflage destruction. A patient in whom a tuberculous pulmonary infiltration appears in the *x*-ray film as soft ill-delimited spots, especially if these tend to confluence, should be treated by rest in bed until the insufficiency of such care is proved by adequate observation. As long as such a lesion, roentgenographically recorded at three months' intervals, continues to show a material retrogression from one quarterly record to the next, the patient must be regarded as one who still needs complete rest in bed. Such a lesion is clearly very unstable. An ambulant patient should be one in whom the lesion is not obviously ill delimited and, in quarterly roentgenographic records, either continues to show retrogression or maintains anatomical stability. Even without the warning of other signs of activity, such as may be found in the blood test, the sedimentation test, temperature, or by physical examination, a patient is not suitable for ambulant care who shows a soft ill-delimited consolidation or mottling, despite evidence of retrogression in quarterly roentgenograms.

Eligibility for discharge should be based on the degree to which the infiltration is reduced to sharp strands and calcium. The younger the patient, the less are the therapeutic and economic obstacles to adequate treatment. Particularly in adolescents and young adults the volcanic character of this disease, its potentiality in them for swift relapse on the one hand and relatively rapid retrogression on the other, should be recognized by the rigid application of a roentgenographic standard of anatomic stability. The younger the patient the more he has to lose or to gain by these alternatives. By so much the more, therefore, should we provide that he is not discharged from close supervision before his lesion is in a stage to support the stresses that heedlessness and economic necessities will bring upon it. Serial roentgenograms are the justification and guide for treatment, and the patient's best protection. Boards of trustees and managers have been known to object to the adequate use of the *x* rays because of cost, which is equivalent to the charges for about three days' care, or, for quarterly films, to twelve days' sanatorium residence in the year. The implication is that merely being in a sanatorium for 365 days in a year is more important than having the medical care accurately adjusted to the needs of the disease every three months and keeping the patient in sanatorium only 353 days of the year. Except for the moribund, is there any group of tuberculous patients who cannot better afford to dispense with a small fraction of their sanatorium stay than to suffer the hazards of uninformed treatment? It is implicit in the foregoing that one must not expect some two or three months' rest in bed to nullify an extensive soft lesion merely because

it has not caused signs or symptoms: There is evidence that of two children with lesions of equal extent the one without symptoms or signs clears more rapidly and completely than the one with clinically manifest disease, but even with the former, time is needed to secure a stable lesion. When unsupported by the warning of symptoms the physician requires, to put the patient in bed or to keep him in bed, the ability to attain, at more appropriate seasons, the Fat Boy's desire, "I wants to make your flesh creep." It is only by the sufficiently early institution of treatment long enough continued that he can succeed in preventing and checking tuberculosis in children and adolescents, and so in forestalling the greater part of the tuberculosis of early adult life. To achieve and establish the benefits of preventive medicine in this difficult but most rewarding field, where the prevention of clinical disease is in turn a means of preventing the spread of infection, even into the next generation, he needs all his resourcefulness, tact, optimism, and the sharpest discrimination in evaluating evidence.

Note.—The use of B.C.G. involves so many considerations that it has not seemed desirable to discuss it in this paper. The figures of Cox[26] and his co-workers give a much lower mortality among children intimately exposed to sputum-positive tuberculosis than are given by French workers. We have reserved B.C.G. for infants born into households containing a person with positive sputum, as a measure whose exact value has not yet been determined. The number of such infants is not large, but, especially if the intelligence of the family is low, the danger is grave.

DIVERTICULA OF THE DUODENUM

BY

S. GILBERT SCOTT, M.R.C.S., L.R.C.P.

D.M.R. AND E.CAMB.

CONSULTANT RADIOLOGIST TO THE LONDON HOSPITAL

(With Special Plate)

THE clinical diagnosis of diverticula of the intestinal tract, excluding possibly those of the proximal and distal sections, the oesophagus, and colon, may be said to be practically impossible without the help of an opaque meal investigation.

By this method these pouches or local bulgings of the intestinal wall have been detected on almost all parts of the intestinal tract; as curiosities, I am reproducing radiographs of minute diverticula of the ileum and appendix (Figs. 3 and 4). The latter brings to mind the old rhyme, "Great fleas have little fleas upon their backs to bite 'em, and little fleas have lesser fleas, and so *ad infinitum*," for the appendix itself may be considered a diverticulum. I have been unable to find any published record of diverticula in these two sections of the intestinal tract.

A definite case of diverticulum of the duodenum, containing stones found by chance at necropsy, was described by Chomel as early as 1710—that is, in the reign of Queen Anne. About one hundred cases had been described up to 1910, none of which were diagnosed clinically. Since the opaque meal examination became possible, the literature on the subject has become considerable.

While granting that diverticula may be present in large numbers in the colon without giving rise to symptoms, my experience leads me to think that those arising from any section of the duodenum eventually produce some form of abdominal disturbance or distress, whether from direct or reflex causes, and in some cases this may even be of an acute nature, although more frequently it is met with as a chronic condition (diverticulitis duodenale). In fact, I now include a duodenal diverticulum in the list of undiagnosed causes of the condition known as "chronic abdomen," which is, in my experience, more often than not, due to one of the following, placed in order of their frequency: (1) duodenal ileus, (2) splenic drag (incomplete enteroptosis), and (3) duodenal diverticulum.

The early diagnosis of any of these is important, for it is in the early stages of development that measures must be taken if the patient is to be prevented from joining the large and pathetic tribe of "chronic abdomens." The majority of these unfortunate cases are but undiagnosed or undiagnosable abdominal lesions.

It will be realized, therefore, that diverticula, especially those arising in connexion with the duodenum, have ceased to be only of academic interest, and call for much more careful consideration and investigation than has hitherto been given them.

It is usual to describe two types of diverticula—the congenital and the acquired. The acquired—namely, those resulting from traction of adhesions, ulcers, etc.—should not, strictly speaking, be placed in the same category as the true or congenital type of sacculation.

All the normal structures and layers pertaining to the duodenum should be found in the true diverticulum, while the individual thickness of the wall is dependent on the degree of distension of the pouch.

As already mentioned, the clinical diagnosis is practically impossible, as the abdominal symptoms are so varied and at times resemble very closely other pathological lesions. In fact, most of the cases I have had to investigate have been sent with the provisional diagnosis of gastric or duodenal ulcer, cholecystitis, or appendicitis—practically the identical list of lesions that the symptoms in duodenal ileus suggest. The causes of symptoms are direct and reflex. As with an appendix, an acute or chronic infection or inflammation may occur. As a rule, however, these changes are only catarrhal, but in some cases suppuration, ulceration, and even perforation are met with.

It is a mistake to conclude that because a diverticulum, found by chance at a post-mortem examination, shows no

evidence of inflammation, that therefore it gave rise to no symptoms during life. Considerable abdominal distress, making the patient's life a misery, may result from the indirect effects of its presence.

In the case here described, the fact that tenderness was elicited over the diverticulum on palpation under the screen, and that a calculus was detected within the lumen, were indications of possible infection. It is not essential, however, for infection to be present to give rise to symptoms. A reflex resulting in spasm of the pylorus or forcible peristalsis of the duodenum, a form of duodenal ileus, may lead to definite attacks of pain and vomiting—often called " bilious attacks," and starting in childhood.

It is by no means uncommon to note a local bulging of the duodenal lumen in the region of the ampulla of Vater.

I do not, however, consider this to be a true diverticulum. Nevertheless, the condition, causing as it does an insufficiency of the sphincter, permits the contents of the duodenum to flow into the bile and pancreatic ducts. Infection may follow, leading to cholecystitis, etc.

It is possible for the pouch to contract and to disgorge its contents if the muscle coat is still well developed and not overstretched. Most of the diverticula I have examined retained their contents for a brief period after the meal was clear of the stomach. This phenomenon suggests atrophy or atony of the muscular coat from overdistension.

As might be expected, the literature on the subject of treatment is somewhat vague. The majority of writers favour surgical intervention, such as excision, invagination, and so on. The physician does not appear to have seriously investigated the possibilities of medical treatment. My impression, however, is that once it has been established that the diverticulum is primarily responsible for symptoms, surgical measures will eventually become necessary.

Process of Development

The literature on the subject of the development of these sacculations is also somewhat meagre. It appears that in the process of development, embryos of about thirty to sixty days show multiple vacuoles or pits, which give rise to local bulging in the wall of the duodenum (Keibel and Mall), but it is open to discussion whether these play any part in the ultimate formation of diverticula.

While granting that a congenital weakness of the wall originally exists, what mechanism is responsible for the gradual pushing out or for the localized bulging of the wall? Obviously there must be some form of internal pressure or stress. Now in the normal duodenum this internal pressure is not high, and certainly not sufficient to create the force required to " balloon " or blow out this inherent weakness of the wall. In most cases a careful investigation of the history will elucidate the fact that, as a child, " bilious attacks " were experienced. These attacks usually persist—three or four a year being usual—until in later years they become more frequent and severe, in most cases the patient seeking medical advice between the ages of 20 and 40.

Now I have been struck with the similarity between the history of diverticula of the duodenum and that of duodenal ileus. Another significant point is that in all the cases I have examined personally duodenal ileus has been present in the first, second, or third degree. This suggests the possibility that here we have the *increase of tension* in the duodenum necessary to produce the gradual local distension or bulge. Is this obstruction, which is noticed at the duodeno-jejunal junction, caused by reflex spasm, analogous to that of the pylorus, in fact a reflex set up by the presence of the diverticulum, or does the diverticulum originate from the combined efforts of a local weakness and a congenital type of duodenal ileus?

Routine Examination

Most of these duodenal diverticula are well developed by the time the patient is forced to seek medical advice, and are readily detected radiographically. The smaller ones, however, necessitate a more careful routine examination of every inch of the duodenal mucosa by radioscopic palpation—the method that should be used in all gastric work. Owing to the fact that many workers depend primarily on films for their diagnosis, many diverticula in their early stages are being overlooked, for although the pouch itself may be large, the opening into it may be small, and unless the contents of the duodenum are dammed up and manipulated into the pouch with the hands on the abdomen, little or none of the meal may enter. This holding up of the duodenal contents by pressure on the distal part should form part of the routine method for examining the duodenum in opaque meal cases. If this method is adopted, there is no necessity to alter the position of the patient, as is advocated by some workers.

A Typical History

The history of the following case is very typical, since the symptoms would fit in with the diagnosis of almost any abdominal lesion.

The girl, aged 22, who was referred to me by Dr. F. Green, was healthy and well developed, but stated that her life was becoming a misery on account of indigestion. As a baby she was very delicate, and her digestion very bad. In fact, she almost died at the age of 6 months. She grew up fairly healthy, but was never quite free from indigestion. She was subject to bilious attacks and had to be careful about her diet.

There is one point in the history of these patients that always makes me suspect the presence of a duodenal ileus or diverticulum—namely, the history of " bilious attacks " in childhood, which they never entirely outgrow.

About two years ago she complained of epigastric pain of a constant and " boring " type. It was almost continuous, and varied in severity.

In New York, this early spring, she underwent an operation for appendicitis. Since then the pain has been, if anything, worse. Burning is a characteristic of these pains, and it is not relieved by food. She vomits now and again with a certain amount of relief. She is hungry, but restrains her appetite and is strict with her diet, being fearful of consequences.

The routine " survey " radiograph demonstrated a small shadow opposite the lumbar vertebrae, suggestive of a calcareous mesenteric gland.

The opaque meal showed a somewhat irritable hypertonic type of stomach. There was no evidence of any gastric lesion. The gastric mucosa was regular. There was a definite pyloric spasm, which was relaxed by gentle abdominal manipulation. The duodenal " cap " was then seen to be normal, and the duodenal contents flowed into a large diverticulum situated at the junction of the second and third parts on its convex or outer aspect (Fig. 1). Most of the duodenal diverticula reported have been seen leading out of the first or second parts, very few from the third part, and nearly all originate on the concave or inner surface.

The small shadow previously seen in the " survey " radiograph, and thought to be a calcareous gland, could now be seen in close relation to the sac itself (Fig. 1). Their respiratory excursion was identical, and they could not be separated by manipulation. The shadow was eventually hidden when the diverticulum became fully filled by the opaque emulsion (Fig. 2). Tenderness was located over the diverticulum. One was forced to the conclusion that the opacity, owing to its close relation to the diverticulum, was probably a small calculus contained in it.

The pouch remained full for about one hour after the stomach and duodenum had emptied.

The patient has shown some improvement under medical treatment, but my experience leads me to think that surgical intervention will eventually become necessary.

BACKACHE IN WOMEN: ITS SIGNIFICANCE AND TREATMENT

BY

CHARLES L. KARK, M.R.C.S., L.R.C.P.

LATE RESIDENT MEDICAL OFFICER, HOSPITAL FOR WOMEN, SOHO, AND GENERAL LYING-IN HOSPITAL, LAMBETH

In the words of Eden and Lockyer "backache is the commonest of all the ailments of which women in indifferent health complain." Notwithstanding the great prevalence of this condition and the vast amount of discomfort and ill-health for which it is responsible, it is extraordinary how little attention has been paid to its pathology and treatment. Whether regarded as a sort of curse which befell Eve, and, like labour pain, a thing to be tolerated, or as a mere symptom of any gynaecological disorder, backache as a pathological phenomenon in itself seldom receives adequate consideration.

It would hardly be an exaggeration to say that the majority of women with retroverted uterus or other disorders of the genitalia who seek treatment principally on account of backache, are not treated for the backache in itself, but for the local pelvic condition associated with it. Nevertheless it has been shown,[1] and it is indeed a common experience, that in a large proportion of cases treatment for the local condition alone fails to relieve the backache. The explanation of this apparent anomaly lies in the fact that backache in the majority of cases, although associated with disorder of the female reproductive organs, is not necessarily a symptom of such disorder, but a symptom of structural and postural changes in the back itself. Moreover, not only does faulty posture account for most cases of backache, but it is probably the underlying cause of much genital pathology. A flattened lumbar arch with bent back gives rise, under certain conditions, not only to backache, but to congested and diseased states of the uterus and adnexa; this statement will be amplified later.

The term "backache" is here taken to denote the common form of ache experienced by some women over the sacro-iliac joints, by others over the lumbar-sacral articulation, and generally in the region of the lumbar-sacral arch; it does not refer to pain due to gross orthopaedic conditions, disease of the vertebrae, or pathological conditions of the viscera apart from the female reproductive organs. This postural backache is the direct result of faulty posture, characteristic in pregnancy with its increased lordosis; common after pregnancy in the non-robust mother, with a diminished lordosis, heavy pendulous breasts, and bent back (the nursing attitude); frequent in all women who have borne children, in frail anaemic girls, especially those whose work involves much sitting or stooping, in all—both men and women—who are confined to bed for lengthy periods.

Anatomical Commentary

The lumbar vertebrae are held in position mainly by the anterior and posterior common ligaments, the supraspinous and interspinous ligaments. These are kept either taut or relaxed according to the attitude of the spine, and are subject to strain. When this strain is constantly repeated or prolonged, aching results. The ligaments are reinforced by the sacrospinalis muscle, which extends from the sacrum to the cervical region. This muscle is a large muscular and tendinous mass, larger in the lumbar region than elsewhere, and it is by its aid that spinal movements take place and the trunk is held erect, the brunt of such action falling on the lumbar-sacral region. When this muscle is strained, therefore, or when it is not strong enough to carry out its normal or increased functions, aching results in the lumbar-sacral region.

Effects of Posture on the Pelvic Viscera

The anterior surface of the lumbar arch, traced from the promontory of the sacrum upwards, forms an inclined plane making an angle of about 30 degrees with the vertical.[2] Thus a shelf is formed which projects between the abdominal and pelvic cavities. As the pelvic cavity inclines posteriorly at an angle of about 90 degrees to the abdominal cavity, the projecting lumbar shelf protects the pelvic viscera from direct pressure of the abdominal contents.[3] When posture is faulty, however, and when, in addition, the anterior abdominal muscles are lax and stretched, the shape of the abdominal and pelvic cavities is modified, the lumbar arch is flattened, the protecting influence of the lumbar shelf is removed, intra-abdominal and intrapelvic pressure is increased, and the functions of the viscera are thus impaired. The effect in the pelvis is to produce a congested state of its contents—a fact of the greatest significance in the etiology of disorders, such as subinvolution, congestive types of dysmenorrhoea, and retroversion. These pathological conditions most frequently commence during the puerperium and the first two or three months following. During this period the abdominal muscles as a result of pregnancy are stretched and weakened, the tone of the sacrospinalis muscle is likewise impaired, the ligaments of the sacrum and lumbar arch are softened and stretched, and posture is consequently faulty. The abdominal viscera press directly upon a heavy involuting uterus, tending to retard involution, and for obvious mechanical reasons forming a potent factor in the production of retroversion.

It will be seen, therefore, that the frequent association of backache with such conditions as retroversion, subinvolution, dysmenorrhoea, congestion of the pelvic organs,[4] is probably due to the existence of a common etiological factor—namely, a weak back, loss of muscle tone, faulty posture. This might serve to explain why the treatment of retroversion and other gynaecological disorders seldom relieves backache unless the back itself is treated, even to the neglect of a local displacement.

Factors in the Production of Backache

Normally the curves and structures of the back are so arranged that the trunk is supported and movements performed with a minimum expenditure of energy. Any deviation from this ideal arrangement renders the mechanism of the back far less efficient, and a much greater tax is imposed on the muscles and ligaments of the spine. Such a condition occurs during pregnancy, when, with an enlarging tumour, and a gradually changing centre of gravity, the muscular and ligamentous structures of the back have to withstand increasing strain in order to maintain the erect posture. Further, where there is a weakness and loss of tone of the back muscles, such as is found after pregnancies, during debilitating illnesses, in frail young women, or during menstruation, especially if there is associated menorrhagia, the strain that the lumbar-sacral spine is normally able to cope with becomes too great for the weakened structures, the arch tends to become flattened, the muscles being too weak or fatigued to support it, ligaments become strained, and backache results.

Analogy between Lumbar and Plantar Arches

The lumbar arch is in many respects analogous to the plantar arch in the foot. In the condition of flat-foot aching is caused by strain on the ligamentous structures of the flattened and weakened arch. This ache can usually be relieved by mechanically supporting the sagging arch. Further, by means of suitable exercises and massage the muscles that normally support the

arch are gradually strengthened until such time as the mechanical support can be dispensed with and the arch maintained by muscles and ligaments that have been rested and restored to function.

Treatment of Backache

In the treatment of backache the most essential factor is the provision of adequate support and rest. This problem is not as simple as it appears at first sight. The support must be adjusted to the exact degree demanded by the patient to afford relief and comfort. In other words, it must relax the strained spinal ligaments and the musculature. A support which is too strong or too weak will fail in its purpose. Rest in bed without an arch support is of little value, and, in fact, is often harmful, as the vast majority of beds sag, the patient lying in a saucer-shaped hollow, with shoulders and feet well above the level of the lumbar arch, which becomes dorsiflexed. An ordinary cushion is of little use, as it cannot be suitably adjusted. It is obvious that the degree of support will vary according to the patient's body weight, the type of arch, and the attitude of the body—that is, the angle it makes with the horizontal at the point where the sacrum impinges on the bed.

To fulfil these conditions a simple apparatus has been devised, which has given most gratifying results in practice. Briefly the device consists of a rubber bag large enough to cover the lumbar arch, to which is connected a piece of rubber tubing sufficiently long to be brought round to the front of the patient. To the free end of the tubing is attached a valve and bulb, similar to that used on a sphygmomanometer. The rubber cushion is easily inflated to the required degree, the valve being used as a control. By its aid the back can be maintained in a constant state of relaxation and freedom from strain; only in this way can aching be effectively remedied.

Generally speaking, faulty posture in bed produces not only much discomfort, backache, disturbed sleep, and avoidable suffering, but other more serious effects. The typical patient propped up in the Fowler or sitting position has his back bent and lumbar arch flattened, with the result that the diaphragm is cramped and its function impaired. Consequently the patient ceases to breathe deeply, the lower lobes of the lungs are not ventilated satisfactorily, and post-operative pulmonary complications are very probable sequels. Finally, in all ailments, whether of the thoracic, abdominal, or pelvic viscera, faulty posture by crowding the organs, producing congestion, and interfering with function, must hamper successful treatment.

Summary

1. Faulty posture is the main cause of backache.

2. It is suggested that it is also a predisposing cause of much disease of the female pelvic organs.

3. An adjustable pneumatic support, devised for the relief of backache, is described.

I am indebted to Dr. James Young, Edinburgh, who has kindly given me permission to state that he has used the cushion device in the Royal Infirmary and in private practice for the last six months and has found it of great value. I am also much indebted to Mr. Leonard Phillips for the facilities he has given me to use the cushion for patients under his care at the Hospital for Women, Soho Square.

A detailed report on the results of this method of treatment will be published. The cushion has been made for me by Messrs. P. B. Cow and Co., Ltd., 46, Cheapside, London, E.C.2.

SEPTICAEMIA AND ENCEPHALITIS IN RELATION TO VACCINATION

BY

ROBERT PRIEST, M.B., M.R.C.P.

MAJOR, R.A.M.C.

In their article on septicaemia and encephalitis in relation to vaccination, published in the *British Medical Journal* of June 21st, 1930, Drs. Temple Grey and Whittaker draw the all-important conclusion that no condition can be fairly described as encephalitis pure and simple unless septicaemia has been excluded as a possible cause by appropriate bacteriological examinations; and, further, that all cases of severe illness occurring in the three weeks after vaccination should be under hospital treatment in order that the special examinations may be performed, and if death occurs the necropsy should include bacteriological and histological investigation of the other tissues as well as those of the central nervous system. These conclusions, and the need for eliminating all other morbid conditions before ascribing any clinical cerebral or encephalitic signs to primary vaccination in an adult, prompt me to record a case, very similar to the first one of those reported by these authors, which was under my care.

Clinical History of Case

A recruit, aged 18, was admitted to the Queen Alexandra Military Hospital on May 27th, 1930, with a history of being ill for four days with headache and dizziness, and some frequency of micturition and diplopia. There was also malaise and loss of appetite, but no nausea or vomiting. He had had influenza in 1929; he had never been abroad. He was vaccinated for the first time in his life on May 7th, 1930, with Government lymph, in two places on the left arm just below the deltoid. On admission his temperature was 104.6°, pulse 124. The vaccination sites showed healthy scabs, with no surrounding inflammation. There were some septic sores on the skin over both insteps, and another septic area, partially covered with an unhealthy scab and surrounded by an area of cellulitis, in the region of the left external malleolus. The toes of the left foot also appeared to be inflamed. The lungs showed no evidence of active disease, but there was some deficiency of air entry and some impairment of note at the left base. The heart did not appear enlarged; there was no thrill, but the first sound at the apex was roughened. Liver edge not felt; spleen not palpable. The patient's mind was clear. The diplopia of which he had complained at the onset was no longer present; there was no squint, and the pupils reacted normally. Abdominal reflexes were absent, knee-jerks sluggish and difficult to obtain, right ankle-jerk absent, left plantar response "flexor," right doubtful. Sphinters controlled. There was slight but obvious ptosis of the eyelids, more marked on the right side.

On May 28th the temperature was 104.4°, pulse 120. Lumbar puncture showed the cerebro-spinal fluid to be under no increase of pressure; the fluid was clear and found to be sterile on culture. Lymphocytes present 6 per c.mm.; no increase of globulin or sugar. The Wassermann reaction proved negative. Blood culture produced a growth of *Staphylococcus albus*. Total leucocytes 14,000; polymorphonuclears 84 per cent., small lymphocytes 8 per cent., large lymphocytes 4 per cent., hyalines 3 per cent., eosinophils 1 per cent. Red blood cells 5,600,000; haemoglobin 80 per cent.

On May 29th the temperature was 104°, pulse 132. The right ptosis was more distinct, and there were now signs of meningeal involvement as shown by neck rigidity, irritability, and hypersensitiveness. There were epistaxis and twitching of the right eyelids, the limbs were much more rigid, plantar reflexes "flexor," abdominal, cremasteric, and epigastric reflexes absent. Arm-jerks were not obtained, except a feeble response in left triceps; knee-jerks absent, right ankle-jerk absent, left brisk. No diplopia, pupils normal. Sphincters controlled. Lumbar puncture proved the cerebro-spinal fluid to be clear and under no pressure.

On May 30th, after a very restless night, the patient was comatose, and showed a very definite paresis of the right face, arm, and leg; the right plantar reflex "extensor," right abdominal reflex absent, left present; some areas of haemorrhage, with some induration, noted over the toes of both feet, under the skin of the left thigh, and a few small pyaemic-looking areas on the back. He was seen by Colonel W. P. MacArthur, who agreed that the condition was one of septicaemia, and, owing to the presence of the systolic bruit, and to the fact that the spleen was now just palpable, formed the opinion that the clinical picture was one of acute infective endocarditis. The patient gradually became weaker, and just before he succumbed on the early morning of May 31st his temperature had risen to 106°.

Post-mortem Findings

At necropsy the two vaccination sites appeared clean and healthy. There were haemorrhages present on the toes of the feet and on the left thigh. The lungs appeared normal. The fluid in the pericardial cavity was blood-stained, numerous vegetations were seen on the mitral valve and on the wall of the left ventricle. No vegetations were seen on the right valves or heart wall. The liver weighed 3 lb. 1 oz.; no macroscopic abnormality noticed. The spleen was enlarged and soft, and weighed 18 oz. In the right kidney there were multiple infarcts; one appeared to be very recent and the others were organized; the left kidney appeared to be normal, and no lesions were seen macroscopically. Microscopical examination of the brain showed thrombosis in the blood vessels, softening of brain substance, and round-cell infiltration. Many of the smaller vessels were congested, and a great excess of leucocytes, mostly polymorphonuclears, was seen within the lumen. On examination of the septic vegetations from the heart valves large masses of Gram-positive micrococci were seen enmeshed within the film covering of the valves.

This case, then, presenting as it did diplopia, headaches, ptosis, the subsequent meningeal signs, rigidity and coma, might have led to a diagnosis of post-vaccinal encephalitis; and, should the question of compensation have arisen, it would have been very difficult to dissociate the two conditions without the careful daily observation while in hospital and without the assistance of the post-mortem findings.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

THE PREVENTION OF PUERPERAL PYREXIA

The following statistics showing the effect of Parke Davis's antistreptococcic puerperal serum as a preventive of puerperal sepsis may prove of interest to those who are engaged in obstetric practice. The apparent beneficial results of this serum can be readily understood by studying the annual returns at Bellshill Hospital before and after its routine administration in complicated cases, and also in normal cases with laceration of the perineum. Our experience has been that the best results are obtained by the administration of the serum in large doses; 50 to 70 c.cm. should be given during labour, or a few days prior to its onset if trouble is anticipated. Procrastination deprives the patient of an opportunity to escape the sequels of infection. Apart from the occurrence of a rash, no inconvenience is experienced. The rash does not appear in some instances, and when it does it varies in frequency and intensity with different batches of serum. We are inclined to regard the occurrence of a rash as a favourable omen. The only other disturbance worthy of note is the not infrequent onset of uterine haemorrhage (15 per cent.) about the eighth to the tenth day, but the loss is not sufficient to create anxiety.

A short explanatory note about the figures is necessary. In 1925 and 1926 serum was not used, but during 1927 and 1928 we began administering this serum, which Parke, Davis and Co. placed at our disposal free of charge for clinical experiment. At this time the output of serum was small, so that only a limited number of cases could be treated. Nevertheless the results were so encouraging that we determined to employ it extensively. During 1929 and 1930 it was given in all complicated cases, and in normal cases where the perineum was torn; the results have been gratifying. Since Mellanby's communication[1] appeared on the value of a diet rich in vitamin A as a preventive of puerperal sepsis in rats, we have advised our patients to partake freely of a diet consisting of fresh vegetables, carrots, cheese, and liver. As this paper appeared only recently, we have not yet obtained a sufficiently large number of cases to estimate if the incidence of puerperal pyrexia in our cases has diminished.

Date	Number of Cases		Puerperal Pyrexia According to B.M.A. Standard	
			Number	Percentage
1925	Confinements ... ... 517 Post-natals ... ... 26 Abortions 122	665	50	7.5
	Of the 517 confinements the number normal was	476	18	3.8
1926	Confinements ... ... 696 Post-natals ... ... 26 Abortions 125	848	55	6.5
	Of the 695 confinements the number normal was	380	11	3.0
1927	Confinements ... ... 726 Post-natals ... ... 47 Abortions 125	898	45	5.0
	Of the 726 confinements the number normal was	432	not known	
1928	Confinements ... ... 707 Post-natals ... ... 32 Abortions 125	864	41	4.7
	Of the 707 confinements the number normal was	432	10	2.3
1929	Confinements ... ... 543 Post-natals ... ... 21 Abortions 139	703	20	2.8
	Of the 543 confinements the number normal was	279	Nil	Nil
1930	Confinements ... ... 700 Post-natals ... ... 40 Abortions 160	900	19	2.1
	Of the 700 confinements the number normal was	308	1	0.3

In 1925 and 1926 no serum was used, and in 1927 and 1928 a limited supply only. In 1929 and 1930 serum was used in all complicated cases, and in normal cases with perineal lacerations.

Radiostoleum is also mentioned by Mellanby as a suitable preparation where vitamin A is required, so we have been using either radiostoleum or adexolin, which contains vitamins A and D.

It seems to us that in obstetrical cases fortifications should be erected early to prevent puerperal infection, and it may be that this aid can be obtained to a large extent by diet and by the administration of serum. The disadvantage is great if the invader is permitted to demonstrate within the citadel.

It is unfortunate that treatment by serum proves expensive, but it should not be forgotten that the victims of puerperal sepsis often have a long and costly illness. The administration of serum during labour curtails convalescence in cases where pyrexia develops.

AN UNUSUAL TYPE OF DIPHTHERIA CARRIER

Recent advances in our knowledge of the immunological processes concerned with the detection of persons susceptible to diphtheria infection and the valuable immunization methods now in use have brought the significance of the disease even more before the public health authorities and medical practitioners. The Schick test has added enormously to our knowledge of the epidemiology. Largely through the extensive investigations and work of Dr. Harries of the Birmingham Medical School, the proportion of immunes among persons who have never had clinical diphtheria, living in different localities and belonging to different levels of society, has been determined. Broadly speaking, a much higher rate of immunity is found among inhabitants of the poorer and more crowded districts; this is presumably owing to greater exposure to subminimal infection with the disease virus and the acquisition of immunity without passing through the recognizable disease.

It would be expected that the possibility of such acquired immunity would be much less among people living in country districts where, although the incidence of the disease may not be low, the chances of contact are much less, even if the conditions of living are poor. The cases here recorded support this contention, and indicate incidentally that the immunization of persons living in country districts is as important as the immunization of town dwellers; it may even be more important. Although perhaps the chances of infection are less among country folk, the clinical course of the established disease is likely to be severe, and may spread rapidly in the household owing to the entire absence of immunity in the other members. It is analogous to measles in the negro races.

Commonly the virulent diphtheria bacilli reside in the throat and nose, and very occasionally in other sites, such as the ear, the eye, the vagina, and wounds. The outbreak recorded below was caused by a member of a family carrying virulent diphtheria bacilli in his left conjunctival sac. The family lived in a farmhouse in a very thinly populated and remote district in Staffordshire. The sequence of events was as follows:

In October, 1929, C. G., aged 12 years, had a mild unilateral conjunctivitis without membrane formation. Under local antiseptic treatment the condition abated. There were no general symptoms. Occasional recrudescence of the conjunctival affection occurred, always remaining unilateral. During the period December 26th, 1929, to January 26th, 1930, one sister and four brothers developed very severe faucial and tonsillar diphtheria. (The sister and one brother have now completely recovered from post-diphtheritic paresis.) Throat swabbings from the mother were negative. The detection of a carrier in the household followed a casual remark concerning the previous eye condition of C. G. Careful examination of his left conjunctival sac showed a few fragments of membrano-purulent exudate, which on bacteriological examination gave a pure growth of diphtheria bacilli. Animal tests showed the marked virulence of the bacilli. The boy had never had any clinical diphtheria infection before. We are therefore of the opinion that he had obtained general immunity from the local conjunctival lesion, and so evaded the more serious illness which occurred in the other members of the family.

The points of special interest in this case are: (1) The persistent high infectivity of the diphtheritic conjunctiva. (2) The absence of immunity in any other child of the family. (3) The suggestion that active immunization of persons living in the country is as important as it is in the case of town dwellers.

I am indebted to Dr. William Fraser of Chasetown for help in collecting the details of this case.

A. VICTOR NEALE, M.D.,
Physician to Out-Patients,
Children's Hospital, Birmingham.

STRANGULATION OF INTESTINE CAUSED BY MECKEL'S DIVERTICULUM

Although Meckel's diverticulum is a fairly common condition it does not very often produce strangulation of intestine, and the following case seems worthy of record.

A man, aged 20, was admitted to the Royal Isle of Wight County Hospital on October 3rd, 1930. Twenty-four hours previously he had been seized with a sudden attack of severe abdominal pain round the umbilicus, which later settled in the right iliac fossa. He had vomited once before admission. There was no history of previous similar attacks.

On admission his face was flushed and tongue furred; temperature 102° F., pulse rate 98. Abdominal examination revealed marked rigidity of the right rectus muscle and tenderness over McBurney's point. A diagnosis of acute appendicitis was made.

The abdomen was opened by means of Battle's incision. On entering the peritoneal cavity a considerable quantity of bright red blood was found. A loop of black gangrenous ileum lay in the right iliac fossa. The strangulation was caused by a band, which was divided. About 18 inches of ileum were resected and an end-to-end anastomosis performed. The appendix was examined and found normal, and the abdomen was then closed. On examination, the band proved to be a Meckel's diverticulum, which opened into the gangrenous loop of ileum.

The patient made an uneventful recovery, and left hospital three weeks after admission.

Shanklin, I.W. J. ALFRED GAYNOR, M.B., F.R.C.S.I.

Reports of Societies

SCABIES AND RINGWORM

At a joint meeting of the Sections of Dermatology and Comparative Medicine of the Royal Society of Medicine, held on February 19th, with Professor G. H. WOOLDRIDGE in the chair, a discussion on scabies and ringworm as transmissible between animals and man was opened by Dr. ARTHUR WHITFIELD.

In the transmission of mange from animals to man, said Dr. Whitfield, the sarcoptes were important, and the animals from which these parasites were most commonly acquired in this country were dogs and, less frequently, cats and horses. Small and toy dogs were more often responsible for transmission to man than large dogs; usually the axillae and inguinal regions were affected first in the dog, then the ears, face, and eyes. In man the arms, trunk, and face were often affected, and the points of the elbows were a common site in both men and dogs. The lesions were minute vesicles on an erythematous base; the acarus might be found occasionally and with difficulty, and was smaller than that responsible for human scabies; to clinch the diagnosis, comparison of the two types of acari was advisable. Cure could be obtained quickly by sulphur inunction, but reinfection might take place indefinitely. Ringworm could also be transmitted from animals to man, the order of frequency of those responsible in this country being the cat, the calf, the horse, the dog, and birds. If the fungus was a microsporon, giving rise to bold rings, an animal origin should be suspected, and especially a cat. Ectothrix came frequently from the horse and the calf; ringworm in these animals was a grossly pyogenic disease, and called into action the defensive mechanisms of the body, with the production of allergy, and a variable immunity.

Mr. A. W. NOEL PILLERS said that the sarcoptes on being transmitted from animals to man might find the soil unfitted after piercing the surface epithelium, and might cease their activities in consequence. Cows were often the source of infection to man, and camels were

frequently responsible in the East. He had seen cases where a pig and a chimpanzee, respectively, had been the original hosts, and infections acquired from the sheep, goat, llama, and wombat had been recorded. It was possible that man might occasionally be responsible for conveying mange to animals, a crop of disgruntled acari, for example, being transferred from the groom to the horse. As to ringworm, much terminological confusion existed. He had sometimes found spores where no lesions were visible.

Dr. W. J. O'DONOVAN reviewed the histological references to scabies. The acarus was described in the twelfth century by Abinzoar, and subsequently by Ingrassi of Naples, by Gabucinus, Laurence Joubert, and other writers of the fifteenth and sixteenth centuries. As far back as 1820, Ernst, a veterinary surgeon in Zurich, had described a case of ringworm in a young girl infected from a cow.

Mr. G. H. LIVESEY said that transmission of scabies from dogs occurred most frequently to women who carried pet or toy dogs. It might affect any part of the body, and personal cleanliness was not a preventive. He described a case in which one blue Persian kitten had been responsible for the infection of sixteen persons with ringworm.

Mr. J. W. HOLMES confined his remarks to the dog and cat. All kinds of follicular mange in these animals could cause an eruption in man, but the sarcoptes were particularly apt to be transmitted. The sites affected in the dog were the head, ears, throat, elbows, the under-surface of the abdomen and thorax, and the outer surface of the tibiae. By scraping deep enough to draw blood he had been successful in demonstrating the parasite in 60 per cent. of cases in the dog. In the cat, mange was usually confined to the head. Scabies had been transmitted to an attendant at the Zoological Gardens by a llama. Ringworm was commonly transmitted from cattle ; a chronic ulceration of the upper lip in cats, due to ringworm, might also give rise to ringworm in man.

Dr. SIDNEY THOMPSON remarked that patients usually proved unco-operative if suspicion was cast on their pets. Owing to the work of the London County Council human ringworm was dying out, and it was therefore essential that attention should be paid to the animal sources of infection. Dr. J. A. DRAKE mentioned a case in which a woman acquiring scabies from her dog developed lesions on all the hotter parts of the body, in the axillae, under the breasts, and under an abdominal bandage. Dr. J. M. H. MCLEOD agreed that a predilection for the hotter parts of the body was shown by the sarcoptes. He had tried to obtain evidence that ringworm fungi might lead a saprophytic existence in the straw of stables, but had not been successful. Mr. PILLERS quoted references to the work of other observers who had found *Microsporon equininum* in the straw of a stable. Dr. A. M. GRAY referred to the experiments of Munro during the war, which had gone to show that the lesions of scabies were due to the acarus in the larval stage. If this were true it would account for the difficulty of demonstrating adult acari in the lesions. In reply to a question, Dr. MCLEOD said he had seen a case in which he believed demodex mange had been transmitted to man from an animal ; but Dr. H. P. FOX considered that this might be a coincidence, since experiments to produce such transmission always appeared to fail.

In his reply Mr. HOLMES said that the adult acarus, usually the female, was responsible for the lesions of scabies, and not the larva.

The CHAIRMAN, in summing up, said that there were cases which pointed to the transmission of mange from cats to dogs. He had never succeeded in transmitting demodex from one dog to another. Larvae were occasionally found on taking a deep scraping, but he believed that they had just been hatched. Llamas and camels had been responsible for transmission to man ; it was almost impossible to cure camels, owing to the thickness of their coats. A case had been recorded where the infection had come from a raccoon. Ringworm was frequently transmitted by cows, which might become reinfected on returning to the same stable after an interval of six or even twelve months.

PHYSIOLOGICAL EFFECTS OF BATHS

At a meeting of the Section of Balneology and Climatology of the Royal Society of Medicine on February 20th, with Dr. F. G. THOMSON (president) in the chair, a discussion was held on possible lines of research which the Section might undertake on the physiological effects of baths.

The PRESIDENT said that an idea had been entertained for some time past that the Section might instigate some combined research of this nature. A good deal of research had already been done, but for the most part it had been carried out by isolated individuals, and consisted of the effects of baths or waters on disease; there had been no attempt at any really well-organized combined research. A great number of the statements found in literature did not carry conviction ; they were made without any confirmatory evidence, and many had been copied from one book to another, and so had become stereotyped and accepted at their face value. Much of the research work also had been on the effect on disease, but what was much wanted, in the first place, was to discover the effect of different hydrological treatments on the normal. Until that was fixed it was impossible to say definitely why certain results were obtained in particular diseases. By such a research some common factors might be found to apply to all waters, and then the waters of different spas might be assessed. The experiments it would be advisable to carry out were: (1) simple clinical experiments, such as the determination of the effects on temperature, pulse rate, sweating, blood pressure, respiration, leucocytosis, and so forth, which might reasonably be expected to be carried out by the practising physician ; and (2) certain experiments concerned with metabolic effects which it would be hopeless for the practising physician to attempt, and which required to be done by specially trained men with laboratory facilities. He added that a great many investigations in the first of these categories could be carried out at special spa hospitals and bathing establishments.

Dr. C. W. BUCKLEY thought that the most important need was for co-ordination of research between the spas and also the clinics and hospitals where physical methods were in use. He gave instances of directions in which research might be usefully applied. A series of observations made at the Devonshire Hospital, Buxton, showed as a general result of baths and mineral water a reduction of blood pressure, sometimes very marked ; but there was no uniformity in this reduction, and it was very difficult to see why, in two cases apparently precisely the same, there should be a reduction in systolic pressure of 10 mm. in one, and in the other a reduction of 20 or 30 mm. In the great majority of cases, with water administered as baths or douches, there was a definite fall in blood pressure, but in a certain number the blood pressure rose. In only one instance, however, was this rise met with in a case in which the pressure was higher than the normal for the age ; in all the other cases where there was a rise of pressure, the pressure had been below the normal. Observations made upon patients in hospital might be assumed to have been taken under

uniform conditions, and therefore to be comparable, but as a matter of fact great variations arose in patients who were out and about, owing to different habits as to exercise and to illicit indulgence in food and perhaps alcohol between meals; while if the patients taken were in bed they could not be described as normal. It was possible, given suitable animals, that the effect of mineral waters might be determined; he believed observations had been made on the development of tadpoles in certain mineral waters, and that was a line of investigation which would be free from some of the ordinary objections. Mineral waters were complex solutions of electrolytes in a state of unstable equilibrium. Stability was probably attained some time after they reached the surface, and this helped to explain why both the internal and external use of such waters was more effective or only effective if used at their source. There were many curious actions of mineral waters which called for further investigation, and if a scheme of research could be drawn up it would be good, not only for the Section, but for the study of balneology as a whole.

Dr. J. B. BURT urged that in deciding on the form of research something of a simple nature should be taken first. He had himself suggested two simple lines of research, one of them the measure of the sedimentation rate, and the other the investigation of temperatures as affected by baths. It might be ascertained whether the temperature went up if a person were kept in a bath for ten minutes, and how the different spa waters compared in this respect with each other and with ordinary tap water. These were lines of investigation which might readily be undertaken, and the co-operation of the big spa hospitals and of the Red Cross Rheumatism Clinic in Marylebone Road might be enlisted. If enough cases were taken the differences due to psychological factors and the factor of diet in respect to the bath reaction would be largely neutralized.

Dr. GEOFFREY HOLMES did not think the problem was quite so simple as Dr. Burt had suggested. These observations on pulse rate, temperature, blood pressure, and so forth had been made before. The fundamental difficulty in research work in balneology was that nothing or very little was known about the physiology of bathing. Balneology was still not taught in the medical schools, with the result that very few people indeed had the slightest interest in the subject, unless they happened to have done spa practice, and once they were settled down in practice it was very difficult to get them to undertake a series of experiments. Two years ago at Harrogate he had been particularly anxious to get some of this work done, and the help of some students from the medical school at Leeds was obtained and a number of experiments made with plain hot-water baths for determining the circulation rate. It was found that in a warm bath the pulse rate rose immediately, certainly before there was any time for the corresponding rise of temperature, and in all these cases, although there might be an immediate rise in systolic pressure, there was a profound drop, as the bath continued, in diastolic pressure. In these experiments also an immersion bath in sulphur water was found to produce much freer sweating and more cyanosis than in plain tap water at the same temperature. In his opinion the work most urgently wanted was research on the ordinary physiology of bathing.

In the course of further discussion, Dr. M. B. RAY promised the co-operation of his colleagues at the Red Cross Rheumatism Clinic, and Dr. A. R. NELIGAN suggested that a very interesting piece of work would be determination of the effects of baths of different temperatures and durations on the pulse rate.

The PRESIDENT said that there was general agreement that it would be a good thing to carry on combined research, beginning with certain simple phenomena associated with different types of baths. Already Dr. Geoffrey Holmes had carried out some valuable observations on the pulse rate; Dr. Burt had made sedimentation tests, and Dr. R. G. Gordon and himself at Bath had carried out certain observations on temperature effects as far as possible under scientific conditions. Dr. BUCKLEY suggested that it might be laid down as a principle that in making temperature tests in baths the continuous self-recording electrical thermometer should be used, and also that it was the rectal temperature which should be taken.

It was agreed to form a small committee to formulate detailed plans for the research, and report further to the Section.

EARLY DIAGNOSIS OF PREGNANCY

At a meeting of the Liverpool Medical Institution held on February 5th, Dr. M. DATNOW read a note on the early diagnosis of pregnancy. He first referred to Liepman, Abderhalden, Fahraeus, and others who had attempted to elaborate tests, and then pointed out how much superior were the recent researches of Aschheim and Zondek, their tests giving results far more accurate than any other so far described. The consideration upon which this test was based might form a starting point for the investigation of many sex problems. The effect upon immature mice of injections of the early morning urine from pregnant women was illustrated by means of specimens and lantern slides showing follicular activity, follicular haemorrhages, corpora lutea atretica, and development of the uterus. Apart from normal pregnancy, hydatidiform mole, chorion epithelioma, ectopic gestation, and, in a few cases, malignant disease, gave a positive Aschheim-Zondek test.

In the discussion which followed, Dr. T. N. A. JEFFCOATE said that his experience of the Aschheim-Zondek test led him to agree that it was very reliable. On the question of the origin of the hormones some observers had recently inclined to the belief that those found in the urine in pregnancy were derived from the placenta rather than from the anterior pituitary. He had recently studied a case of pregnancy in which both ovaries had to be removed at the sixteenth week. There was no change in the amount of oestrin present in the urine after operation; this pointed to the fact that the placenta, rather than the ovaries, was the chief source of the oestrin which is excreted in the urine during pregnancy. The solution of the problem of the origin of prolan A and B was more difficult, since animal experiment was excluded by the fact that the urine of pregnant animals did not give the reaction. Prolan A was found to be present in the urine of women after sterilization, at the menopause, and in some cases of carcinoma; the occurrence of this hormone in the urine in these conditions did not, however, affect the reliability of the test as used in the diagnosis of pregnancy, since it was present in much smaller quantities. In conclusion, Dr. Jeffcoate said that, provided the investigator was given the clinical data as a guide, it was possible to be correct in the diagnosis of pregnancy in almost 100 per cent. of cases. Dr. ARTHUR A. GEMMELL sounded a warning note against accepting the test as always accurate. In a very limited number of cases he had had two in which the test was incorrect. He stressed the fact that the test was not a test for pregnancy, but for the presence of living chorion, and that its reported result must be carefully considered in connexion with the clinical findings.

After the reading of a note by Dr. T. GUTHRIE, entitled, "Two abnormalities of the hyoid arch," Dr. I. HARRIS gave a paper on cardiac output and oxygen utilization in heart disease. Data were collected from different types of heart cases in regard to consumption of oxygen, output

of CO_2, the patient's reaction to exercise, oxygen requirement, oxygen debt, CO_2 and oxygen in venous blood, cardiac output, heart rate, and number of respirations. Cardiac output was determined by the CO_2 method. Determinations were undertaken under resting conditions and after standard exercise. It was found that under resting conditions oxygen consumption, percentage of oxygen utilization, and the cardiac output, with a few exceptions, were normal. Exceptional cases which showed an abnormally small output gave an abnormally high percentage of utilization, the conditions standing in inverse ratio to each other. The size of cardiac output broadly stood in some relation to the amount of oxygen consumption, but a case in which the cardiac output was large and oxygen consumption moderate gave a low haemoglobin percentage, the large output evidently compensating for a poor carrying capacity of oxygen of the blood. The cardiac output was increased to a much smaller extent in heart cases after a standard exercise in comparison with normal cases; while the percentage of oxygen utilization had greatly increased in the diseased heart after exercise, the percentage of utilization remained the same in the normal heart under resting and working conditions. Thus oxygen utilization and output stood in inverse ratio to each other. This constituted a very important factor in estimating cardiac reserve power. Further, the oxygen consumption, as the result of work, in heart cases was greatly increased above normal, and the time before the oxygen consumption became normal again was greatly prolonged. The CO_2 content of the blood in heart cases under resting conditions was lower than normal. This was contrasted with oxygen saturation, which was practically normal in all these cases; CO_2 being an important stimulus to the circulation, the rationale of giving oxygen in heart cases was discussed. In the diseased heart, stroke volume increased after exercise to a less extent than in the normal; in an advanced case of heart disease it did not increase at all. The reaction of stroke volume to exercise was a definite measurement of cardiac reserve power. The diseased heart increased its minute volume by increasing the number of beats, the normal heart by increasing the size of the single stroke volume. The importance of this method was so great that the Liverpool Heart Hospital had created a special department for the routine examination of suitable cases.

A RETROSPECT OF GYNAECOLOGY AND OBSTETRICS

At a meeting of the Edinburgh Obstetrical Society, held on January 14th, with the vice-president, Dr. JAMES YOUNG, in the chair, Professor ARCHIBALD DONALD of Manchester read a paper entitled "Then and now."

Professor Donald began by saying that the thirty years between 1880 and 1910 represented the most eventful period known in surgical history. He described the conditions at St. Mary's Hospital, Manchester, when he first entered it as resident surgical officer in 1884. The out-patient department at that time provided opportunities for unrivalled diagnosis. Among the many cases reported every day were large abdominal tumours. Local applications and the use of the sound and pessary were the common forms of treatment for the minor gynaecological cases. Operations in the hospital consisted of perineal and fistula repairs, and the removal of polypi. Four types of colporrhaphies—two anterior and two posterior—were attempted at that time, but the posterior operation was abandoned, as it involved the opening of the pouch of Douglas, which was supposed in those days to be a very dangerous risk. No curettages were done, and dilatation of the cervix was effected only by means of tents. Ovariotomy was the only major operation performed, but the mortality was very high. It was of historical interest that Charles Clay, who was the father of ovariotomy in Europe, was associated with St. Mary's Hospital for a time. Operations for fibroid tumours were attempted only at a much later date. The first treatment was the extraperitoneal treatment of the stump, which was responsible for a mortality of 62.5 per cent. In 1883 the removal of the appendages was advised by Tait, and this operation, along with Apostoli's electric therapy, delayed for a considerable period any advance in the treatment by hysterectomy. In 1891 myomectomy was carried out at St. Mary's Hospital, and in 1892 vaginal hysterectomy was first performed for a fibroid, though it had been done three years previously for a carcinoma of the cervix. The combined abdominal and vaginal operation was performed in 1892, and the subtotal hysterectomy—the precursor of the present operation—was first attempted in the following year. Reference was made to Cullingworth's hard struggle with regard to the operative treatment for inflammatory diseases of the appendages and to the many derogatory statements that had followed the reading of his paper before the Royal Society of Medicine. The combined anterior and posterior colporrhaphy along with the amputation of the cervix was first attempted by Professor Donald in 1888, and catgut was very quickly substituted for silver wire. In referring to the after-histories of his first three cases, Professor Donald showed how satisfactory were the results. These were the first cases in which buried catgut had been used. The operation was modified slightly by Fothergill in 1908 in regard to the amputation of the cervix, but buried sutures were not used in Fothergill's operation.

With regard to obstetrics there were two thousand to three thousand district cases a year which were attended by midwives and doctors from St. Mary's Hospital. Even in those days ante-natal care was practised, careful histories being taken and the urine being tested frequently during the pregnancy. Accommodation in the hospital was very limited for midwifery cases, nevertheless 150 obstetrical operations were performed every year. Turning to the present day Professor Donald attributed primarily to Lister the great advancement that had been made. He considered that sepsis, which followed antisepsis, was the chief factor in the comparative safety of surgery to-day, and that the Trendelenburg position allowed a great advance in pelvic surgery. He feared that there was an irreducible mortality in abdominal operations, regarded generally, of 2.5 per cent. In his opinion surgery had not reached its limits, for radium and x rays were still in their infancy, and anaesthetists were opening up new fields by their research for methods of reducing shock. Professor Donald then described how he had noted clinical cases, now described as endometriomata, as early as 1917, and though these were carefully examined microscopically, unfortunately the endometrial lining had been destroyed on account of their large size. The whole situation was cleared up in 1921 by J. A. Sampson, who showed microscopically that the disease was caused by fragments of endometrium which had been carried through the tubes to the pelvic cavity. This was also demonstrated later by Dr. Bailey of St. Mary's Hospital. Professor Donald considered that the practice of midwifery stood much where it did forty years ago, though there had been two great advances—namely, antenatal care and Caesarean section; but the latter, after all, was a result of surgical progress. Maternal mortality was still 4 per 1,000, and the interim report of the Departmental Committee for Maternal Mortality and Morbidity revealed that nearly half the fatal cases from sepsis

followed normal labour. Referring to disinfection, he stated that lysol alone had been used in a strength that was of little use as an antiseptic agent in a very large proportion of the fatal septic cases; he considered that the substitution of mercurial preparations in sufficient strength would have a very marked effect in reducing sepsis. Commenting on medical training, he said that the student was trained in aseptic technique in a well-equipped operating theatre or labour ward, whereas when he had to attend cases in the district, or later in his general practice, this aseptic technique was impossible, and an antiseptic technique had to be substituted for it. He contended that antiseptic training was necessary to prepare students for the conditions met with in private practice, and that the three essentials which must be observed were: the disinfection of the hands and arms, the disinfection of the patient's perineum and vulva, and, lastly, the care of the perineum and vulva after labour. He did not regard gloves as essential. Professor Donald concluded his address by remarking that there was no doubt that the results in the larger maternity hospitals had improved in recent years, and that the epidemics of puerperal sepsis were now countered by early and radical measures. In his view an up-to-date maternity hospital should consist of three blocks—one for booked cases, a second for suspect cases, and a third for septic cases, and that each of these should be managed quite independently.

VACCINE THERAPY

The annual meeting of the Association of Clinical Pathologists was held at the Hospital for Sick Children, Great Ormond Street, on January 31st, with Dr. D. NABARRO in the chair. The meeting was devoted to a discussion of vaccine therapy.

Dr. C. E. JENKINS opened with a paper on general principles. He dealt with the contention that vaccine therapy must in the nature of things be useless because, in the face of an infection, it was futile to expect the body to respond to further doses of the infecting organisms. Dr. Jenkins referred to this attitude as the "pint pot" theory; he regarded it as entirely fallacious. The aim of vaccine therapy should be to induce an immunogenic response on the part of tissues other than those actually invaded by the infecting organisms. He further contended that the response of the tissues to dead differed from that to living organisms. Living organisms, in virtue of their being alive and able to produce bodies of the nature of aggressins, could to some extent inhibit the production of immune bodies by the tissues. Dead organisms had no such inhibitory effect. The aim of vaccine therapy should be to convert a patient susceptible to the attacks of a particular organism into a refractory subject.

In the discussion that followed this paper, several members spoke of local immunization, and recorded successful results in the local use of vaccines in pyorrhoea, sycosis, and other conditions.

Dr. D. EMBLETON, speaking on the investigation of cases with a view to vaccine therapy, expressed the opinion that no proof existed of the therapeutic value of vaccines. He laid stress upon the necessity for a thorough general examination of the patient as a preliminary to any attempt to prepare a vaccine. Various members disagreed with Dr. Embleton as to the absence of proof of the therapeutic value of vaccines. Dr. JENKINS stated that in his opinion, although statistical proof might be lacking, and might in the nature of the case be impossible to obtain, there was overwhelming evidence in favour of their value. Dr. DYKE observed that many of the most successful results of vaccine therapy, as in the case of boils, the common cold, and so forth, were obtained, not by curing the existing lesion, but by preventing the occurrence of future ones; in this respect such treatment might be regarded as prophylactic rather than therapeutic.

Dr. A. RENSHAW outlined a very full scheme for the investigation of rheumatic cases with a view to their treatment by vaccines. He said that the earlier the case was seen the greater measure of success in treatment was to be looked for; and he laid great stress upon the discovery and eradication of focal sepsis. Various members, though agreeing upon the importance of thorough investigation of the case, considered that Dr. Renshaw was inclined to go too far in this direction, and that to subject the patients to the extensive routine investigation demanded by him was unreasonable. Dr. S. MILLER and others drew attention to the disturbance of carbohydrate tolerance and of the liver function as revealed by the levulose tolerance test in rheumatic cases. Dr. Renshaw expressed the opinion that a disturbance of carbohydrate tolerance was common, and that such cases, contrary to the general opinion, usually did better with limitation of the carbohydrates and plenty of meat in the diet.

Dr. A. F. WRIGHT considered briefly the general considerations governing the preparation of vaccines. The antigen used should be altered as little as possible by subculture; and he recommended killing by heat and standardization by opacity. Other members expressed the opinion that killing of the organisms was better carried out by chemicals than by heat.

Dr. CRONIN LOWE described his technique for selecting organisms for preparation of vaccines by means of blood selection. Swabs from the patient were sown into the patient's own blood, the organism which grew in the blood being that chosen for preparation of the vaccine. Dr. A. G. SHERA laid stress upon the importance of the inclusion of the toxic products of the organisms as well as the organisms themselves in vaccines. He regarded this as being of particular importance in the case of the staphylococci and streptococci. It was his custom to add to his emulsions of organisms, filtrate from broth cultures to the extent of 5 per cent. Dr. JENKINS described his technique for the preparation of "residual" vaccines.

SILICOSIS

At a meeting of the Sheffield Medico-Chirurgical Society, held on February 4th, with the president, Professor GRAHAM SIMPSON, in the chair, Professor ARTHUR HALL gave an account of his recent visit to Johannesburg, when, at the invitation of the International Labour Office of the League of Nations, he was one of the delegates from Great Britain at the International Conference on Silicosis. He pointed out that Johannesburg had been selected because in that city the incidence of silicosis amongst gold miners, and the medical organization for dealing with it there, were on a far greater scale than in any other centre.

Professor Hall said that in 1843 a very full account of "grinders' phthisis" was published by Dr. Calvert Holland, one of the then physicians to the General (now Royal) Infirmary. More recently a further source of silicosis had arisen in the city and district in connexion with the working in ganister, found in abundance in the neighbouring valleys. He explained the difficulties which had been met with in the country in the application of the Workmen's Compensation Act to cases of silicosis on account of the long latent period and the insidious onset and development. The problem of apportioning the onus of compensation in a disease which might not show itself until a considerable time after the workman had perhaps left the industry in which it was acquired was

obviously no easy matter. The speaker dealt with the work of the South African Miners' Phthisis Medical Bureau, and showed a large number of lantern slides.

There were some 15,000 white miners employed in the Rand gold mines, and each of these had to undergo an initial complete examination, both clinical and radiological, before being allowed to work underground. A similar examination was necessary every six months during employment; thus the number of daily examinations at the bureau was very large. For this work eight whole-time medical officers were required, together with a radiologist, a pathologist, and the necessary clinical staff and assistants. Besides the white miners, about 200,000 natives were employed underground. These men stayed in the mines only for a period of some twelve to eighteen months. This time was found to be too short to produce signs of silicosis, and it was therefore unnecessary to submit natives to the bureau for periodic examination. They were fully examined clinically, however, by a special medical board before admission underground. When a white miner was first found by the bureau to show definite signs of early silicosis, he was informed of the fact and could, if he wished, stop work and receive compensation at a certain rate. If he did so he continued to come up for re-examination at stated intervals, and, if the disease caused a growing disability, the compensation was increased according to a definite scale. If, however, he chose to continue at work underground, he could do so, it being stipulated that compensation on leaving would not be more than it would have been at the first assessment. Men found to have tuberculosis, or tuberculosis with silicosis, had to leave the industry at once; they received compensation.

Regarding the actual work of the conference, reference was made to the difficult problem of dust prevention, and to the impossibility of applying identical methods in the various industries owing to the great difference in working conditions. In connexion with diagnosis, a series of slides and photographs were shown which had been collected for the conference. These illustrated the pathological features (both macroscopical and microscopical), and the *x*-ray findings, in gold miners' silicosis.

At the annual meeting of the Devon and Exeter Medico-Chirurgical Society, held on January 29th, Dr. F. A. ROPER occupied the chair in the absence of the newly elected president, Dr. J. R. HARPER. Several patients were shown and their diseases discussed. In a case of myasthenia gravis occurring in a woman, aged 31, the possibility of encephalitis lethargica had been considered, Dr. R. N. CRAIG suggesting that if there was any doubt remaining, the removal and section of a small fragment of muscle would make matters clear, as the lymphoid bodies between the muscle fibres could be demonstrated. An interesting case of albuminuric retinitis was also shown. The patient was a woman, aged 41, who had been married two years, and in the first twelve months had had a miscarriage, eclamptic symptoms and albuminuria developing in the second month of the second pregnancy. Total blindness necessitated induction of labour, after which vision improved slowly. Mr. G. P. HAWKER, who had examined the fundi, said that owing to the chronic nature of the neuro-retinitis, the affection would probably recur, thus the prognosis was very grave. A case of polycythaemia vera in a man, aged 60, was demonstrated by Dr. ROPER, who said that in August, 1930, the red blood cells had been 12,000,000, white cells 23,400, and haemoglobin 110 per cent. Treatment had been limited entirely to that with acetyl phenyl-hydrazin, and *pari passu* the red blood cells became reduced to 5,344,000. In reply to questions, Dr. Roper advised caution in giving the drug; the third course had had to be stopped, since the red cell count had fallen to 4,650,000.

Reviews

THE CEREBRO-SPINAL FLUID

In spite of the extensive research which has been devoted to the subject, especially since the beginning of the present century, it is evident that our knowledge of the nature and function of cerebro-spinal fluid is still very imperfect. In his valuable monograph[1] Professor V. KAFKA emphasizes the fact that research has hitherto been diverted from the study of cerebro-spinal fluid itself to its more practical application to clinical medicine, and especially to the often doubtful interpretations of the varying appearances and composition of the fluid and their relations to the diagnosis of diseased conditions. Concentrating primarily on the appearance, composition, origin, and function of normal cerebro-spinal fluid, he has endeavoured, by collecting and reviewing the many available observations on the subject, to define more clearly the, as yet, uncertain limits of the normal and pathological fluids. The greater part of the book is concerned with the general characters of cerebro-spinal fluid, its macroscopic and microscopic appearances, its chemical composition, and its physical and chemical properties. It provides a great mass of information of rather unequal value, including many conflicting statements by different observers which are not sufficiently commented upon; indeed, the astonishing number of references to the work of others, together with the relative scarcity of paragraphs and frequent abrupt changes of the subjects discussed, have reduced this section to a catalogue, involving much repetition, and interruption to intelligent reading. Possibly some of the confusion could have been avoided by freer employment of tables.

After a useful chapter on the anatomical relations and boundaries of the fluid, the author discusses the place of origin, the nature, and function of the fluid. He considers it is now safe to assert that under normal conditions the cerebro-spinal fluid probably arises solely from the choroid plexus, which is not only the site of its formation but also of its "permeability." How far, if at all, this is shared by the tissues cannot as yet be completely answered. In certain pathological states the choroid plexus is certainly not the only site of origin of the fluid. Whether the fluid should be regarded strictly as a secretion or rather as an exudate or transudate is not clear. Professor Kafka considers that the process of the formation of cerebro-spinal fluid is very complex, for the most part physico-chemical and only to be described as biological; perhaps the expression "absorptive secretion" (Fleischmann) conveys the best idea. The fluid is chiefly a pressure-regulating mechanism; it provides also an optimum medium for the living nerve tissue; it acts as a defence against infection.

This monograph will be of great use as a book of reference; the bibliography, which extends to upwards of 100 pages, is conveniently arranged in sections corresponding with those of the text.

GASTRO-DUODENAL RADIOGRAPHY

During the last few years a number of atlases of radiology have appeared. As a rule they are expensive and are written for the use of experts. The little book by RAMOND and JACQUELIN[2] will appeal to a wider class of reader. It describes in small compass the various appear-

[1] *Die Zerebrospinalflussigkeit.* Von Professor Dr. med. V. Kafka. Leipzig und Wien: F. Deuticke. 1930. (Pp. x + 400; 46 figures. M.30.)

[2] *Radiologie de l'estomac et du duodénum.* Par Félix Ramond et Charles Jacquelin. 2e édition. Paris: N. Maloine. 1930. (Pp. 206; 167 figures. 35 fr.)

ances on the *x*-ray screen of the stomach and duodenum under normal and pathological conditions. The descriptions of apparatus and technique are packed into a few pages, readers being referred for fuller information to other and bigger books. The authors insist that a full clinical examination of the patient should be made before the *x*-ray examination; and that a complete *x*-ray examination is necessary, even though only a single organ seems affected. Much more is gained by observing the contours and movements of the stomach on the screen than by photography. The authors advocate the use of radiographs for confirmation of detail, but themselves prefer a rapid sketch of the screen appearance made on transparent paper placed in front of the screen. Throughout the book the illustrations are sketches made in this way. The usual ground of the normal position and shape of the stomach is covered, and succeeding chapters describe appearances in pathological states of stomach, duodenum, and adjacent organs, such as the gall-bladder. The shadowgraphs are so clear that the text can be followed easily with only a small knowledge of French. The descriptions are usually adequate, though modern advances in defining the gastric mucosal folds in chronic gastritis and its associated states are scarcely mentioned. The book may be read with benefit by practitioners who wish to interpret the *x*-ray films sent to them by radiologists. Radiologists themselves will not find much new to interest them, though the illustrations by shadowgraph are well worthy of study.

SURGICAL EMERGENCIES

A book on surgical emergencies should be written by a young man who is actually engaged in the practice of surgery, and whose views are not mellowed by time but sharpened by immediate experience. In *Emergency Surgery*, vol. i,[3] by Mr. HAMILTON BAILEY, we have such a book, and, as he remarks in the preface, this subject has been engaging his attention over some years. This volume deals with the emergency surgery of the abdomen, female generative organs, and the genito-urinary system. A second, in course of preparation, is to include the other systems.

The book is clearly written, the operations are explained in detail without unnecessary padding, and the author's views are set forth in a dogmatic manner which is no disadvantage in the majority of instances, as it avoids alternative methods which may be merely confusing to the reader. In regard to acute appendicitis the reviewer disagrees with the author's views on delayed operation after forty-eight hours, even when the patient is watched on the "threshold of the operating theatre," and as the book is especially written for the "comparatively isolated surgeon" it would perhaps have been better not to stress the Ochsner treatment. The abdominal section is well done and the reasons for procedure are clearly put forward, especially the remarks on gastro-enterostomy in perforated gastric and duodenal ulcers, although suprapubic drainage is not in our opinion so necessary as the author makes out. His views on the treatment of severe haematemesis from a chronic gastric ulcer are sound, and there appears adequate reason for stressing the advantages of transfusion and retransfusion in these cases, even though the ulcer is still bleeding. The sections on the kidney, bladder, and prostate are also clearly written and concise, and here the surgeon will find many useful hints for dealing with awkward situations. Throughout the book there is a commendable absence of the use of intricate surgical instruments, and there is much to be said for Mr. Bailey's opinion, stated in the first few pages, that catgut of a higher number than 0 is rarely necessary.

The illustrations are numerous and very clear, and are reproduced in the excellent manner that we now expect from the publishing house of Wright.

[3] *Emergency Surgery*. By Hamilton Bailey, F.R.C.S. Vol. i: Abdomen and Pelvis. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (Pp. xviii + 380; 324 figures. 25s. net.)

A HEALTH CENTRE

University settlements and kindred organizations for social work are usually founded on a religious basis, though some of them have a medical department or certain medical activities associated with them. There is no reason, however, why valuable and extensive social work of the same type should not be founded on a health basis, with medical activities as the main, the central, the essential portion of the work. An interesting account of the inception, the development, and the practical outcome of such a medical settlement (or, as the authors call it, "the pioneer health centre") will be found in a small volume entitled *The Case for Action*,[4] by Drs. INNES H. PEARSE and G. SCOTT WILLIAMSON. It is commended to the notice of readers by Lord Moynihan and the Master of Balliol. The work of the health centre set out in this book is indeed commendable on many grounds, and noteworthy because, both in its doing and in its description, stress is laid on certain principles which, while they have been recognized for a considerable time, have of late years occupied a place of growing importance in the sphere of health and of medicine. The three most fundamental of these may perhaps be stated thus: not only must the preventive aspects of medicine be continually borne in mind, but the development of all functions of the body and mind to the greatest extent possible must be the aim; medical work and social work, the medical practitioner and the social worker, constitute an essential partnership; and psychological knowledge and considerations are at least as important as knowledge of the physical frame and its abnormalities in dealing with individual and family health. Other points, of a somewhat different character, that are brought out, are the importance of the father in family life and in the rearing of children, and the advantage of throwing as much responsibility as possible upon parents and individuals instead of relying wholly or mainly on State or communal action.

Now none of these things is quite a new discovery, and every one of them has been given practical recognition as a part of medical work of various kinds, sometimes very extensively, though perhaps not with such full co-ordination as has been effected and described by Drs. Pearse and Williamson. It is a pity, therefore, that the book is pervaded by a sort of exaggeration, and that there should be some appearance of depreciation of the work of private medical practitioners, of hospitals, and of county or municipal centres conducted on the same principles within their respective spheres. It is fair to say that the authors do not actually blame such practitioners, institutions, or organizations; they merely assume that circumstances make it inherently impossible for them to do good work on similar lines. As an instance of exaggeration is this: "Official reports state that over 1,000,000 children in this country are too unfit to take advantage of the education offered them by the State and paid for by the taxpayer." Again, "Owing to the provision of a periodic medical overhaul disease was discovered and brought to treatment perhaps on an average six to ten years before in the ordinary course of events it would have reached a doctor's consulting room." On what evidence can such a statement

[4] *The Case for Action*. By Innes H. Pearse, M.D., B.S., and G. Scott Williamson, *M.C.*, M.D.Ed. With preface by Lord Moynihan, K.C.M.G., C.B., and A. D. Lindsay, C.B.E., LL.D. London: Faber and Faber, Ltd. 1931. (Pp. xii + 171; illustrated. 5s. net.)

be based, even if much virtue be found in " perhaps "? Concerning the general practitioner, the following statements, with others of like implication, are made: " Even the doctor is no longer the family doctor. He is now the panel doctor dealing with the insured members of the family only." Speaking of the patient discharged from hospital after a serious illness, " Who is to look after him? The hospital is too occupied with the next urgent case. His panel doctor, whom he has never visited, knows nothing about him or his illness. The panel doctor is fully occupied treating the sick and has no time to give to those who appear well." Speaking of married women with uterine symptoms, " A private doctor, particularly a man, is reluctant to make the necessary examination unless the need is urgent and pressing." Speaking of an inveterate smoker, a woman who had severe laryngitis, " The woman would not have been content with mere advice from any doctor she had called in to treat her."

Passages like these, giving a wrong idea of what we believe to be the usual relationship between doctor and patient in general and insurance practice, could be multiplied. The authors seem to take it for granted that in ordinary working-class medical practice no attempt is made to keep patients well, no attention is paid to them unless they are definitely ill, no correction of bad habits is suggested, and no account is taken of home conditions or family relationships. This assumed state of affairs, in both private and hospital work, is described as "deplorable yet inevitable." The authors may be comforted: the inferences they have drawn from personal observation are not of universal application. Apart from the matters we have criticized, their book is valuable and suggestive in its description of an experiment conducted on correct principles and sound lines.

FIRST LINES ON CANCER

Cancer and Scientific Research,[5] by Dr. BARBARA HOLMES, is one of a series entitled "The Sheldon Books of Popular Science," edited by Dr. and Mrs. Needham. The editors remark in a prefatory note that our present age is dominated by science and that therefore it is desirable for the general public to know something of the methods and outlook of science. The purpose of the series is to provide such information written by scientists in untechnical language. Sir Frederick Hopkins contributes a preface to the volume under review in which he expresses the hope that the instruction of the lay public in the facts concerning cancer may do something to dispel the half superstitious element in the dread which this malady inspires.

Mrs. Holmes has endeavoured to give a simple account of the salient facts established about cancer. The book opens with an account of the history of the disease and of the evidence concerning its present incidence. The influence of occupation and heredity on the occurrence of cancer is discussed. Finally, a short account is given of the points of chief interest that have been established by the prolonged researches on experimental cancer and tissue culture. This short summary indicates the width of the field with which the book deals, for the problems arising involve vital statistics, laws of heredity, biochemistry, cytology, and even the theory of immunity. The author shows remarkable skill in explaining the salient points in simple language.

The two essential things about a book of this kind are, first, that the picture it presents should convey a correct general impression of the subject, and, secondly, that it should be readable. Mrs. Holmes's little book passes both these tests with credit. Though intended primarily for the lay public it can be recommended to the medical profession, for not only is it interesting, but those who are not specialists in cancer research will find here a large amount of information that probably is new to them.

BIOLOGICAL DATA AND BELIEFS

In his book *The Progress of Life*[6] it is the avowed intention of Professor MEEK " to indicate a way to recover that elasticity of conception of the process of evolution which the behaviour of protoplasm invites and which the germ-plasm theory of development has for so many years prevented." The endeavour to denude theories of superfluous hypotheses and to expose the weakness of false doctrines is an admirable objective, and having read the preface we looked forward hopefully to a broad and stimulating exposition of evolutionary concepts. But we were disappointed. *The Progress of Life* is an encyclopaedia of biological facts, chiefly relating to morphology, but for the reader there is a serious risk that, having studied it, he will fail to see the wood on account of the trees. It may be that the author has succeeded in his purpose, but the impression which remains after carefully reading this book is that he has been embarrassed by the extent of his own knowledge. He introduces such a vast array of material to exemplify his argument that the reader is bewildered, and searches in vain for a sustained and continuous theme. This is much to be regretted, as there are many who will agree that the time has come when it is desirable to survey the claims to validity of the several " biological creeds " to which the author refers.

NOTES ON BOOKS

The third edition of the *Manual of Physiology*,[7] by LYLE and DE SOUZA, has now been published. Considering its size it contains an astonishingly large amount of matter, well expressed, and on the whole with due emphasis on the essentials. It will certainly serve as a good synopsis of the subject. In the next edition the revision might be even more thorough. The small book, for instance, tends to be rather overloaded with chemical formulae, and there is included a certain amount of matter of little value for the medical student. Some reference, too, in the present edition might have been made to the modern work on the apparent relationship between the activity of the ovary and the pars anterior of the pituitary, to the effect of liver extracts on the formation of the erythrocytes, and to blood grouping—all subjects of interest in applied physiology.

In a practical little work, clear and precise, Dr. H. JUMON has written a most interesting monograph on Infantile Asthma and its Associated Reactions.[8] He confines his investigations to true asthma occurring in children at some time in the first six years of life and disappearing at puberty or shortly before it. He discusses the associated occurrence of skin irritation, and goes fully into the matter of acetonaemia, which he considers is at the root of most of the trouble. Generally speaking, colloidoclastic shock, chiefly influenced by weather conditions, is found as the basis of the attacks; the inherited asthmatic " soil " demonstrates its peculiarities by insufficiency and by instability of the vegetative nervous system. Dr. Jumon regards this special form of infantile asthma as a syndrome, which he calls " syndrome arthritique infantile." He has

[6] *The Progress of Life*. By Alexander Meek, D.Sc. London: E. Arnold and Co. 1930. (Pp. vii + 193; 10 figures. 10s. 6d. net.)

[7] *Manual of Physiology*. By H. Willoughby Lyle, M.D., B.S., F.R.C.S., and David de Souza, M.D., D.Sc., F.R.C.P. Third edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1930. (Pp. xvi + 820; 138 figures, 3 plates. 16s. net.)

[8] *L'asthme infantile*. Par H. Jumon. Paris: N. Maloine. 1931. (Pp. 139. 18 fr.)

nothing new to say about treatment, but he discusses critically the numerous remedies already well known to the profession.

The monograph on Epidemic Infantile Paralysis,[9] forming volume xi of Lehmann's medical textbooks, by Professor FRITZ LANGE, the well-known orthopaedic surgeon of Munich, is based on his thirty-five years' experience of the disease, and claims to be the only comprehensive modern German work on the subject. The first three chapters and the last, which between them deal with the history, pathogenesis, and symptomatology of poliomyelitis and other forms of infantile paralysis, and general treatment, will appeal to the physician. The greater part of the book is taken up by a consideration of the orthopaedic treatment of poliomyelitis, particularly the transplantation of tendons and the use of artificial ligaments, consisting of strands of silk, which Lange was the first to introduce. The text is liberally interspersed with excellent photographs, and eight coloured plates are appended.

The well-merited popularity of the Compendium of Social Hygiene[10] by Professor B. CHAJES, of which a revised and enlarged third edition has recently been published, is shown by the fact that it has been translated into Polish, Russian, Japanese, and Ukrainian. After an interesting introduction dealing with the scope and history of social hygiene the author discusses in turn medical statistics, the social hygiene of housing, feeding and clothing, tuberculosis, venereal diseases, alcoholism, the social hygiene of childhood, industrial hygiene, eugenics, and sanitary organization in Germany, where a Ministry of Health is still unknown in spite of its existence in at least thirty other countries. A bibliography of 114 references to exclusively German books and periodic literature dealing with social hygiene is appended. The text is interspersed with numerous tables, which will be of value even to those whose knowledge of German is imperfect.

Among the numerous drugs discussed in Part III of *E. Merck's Annual Report*[11] for 1930, the following have especial interest. Oral tetragnost is the name given to a new preparation of sodium tetra-iodo-phenolphthalein suitable for oral administration. The unpleasant side-effects apt to result from intravenous injection of this drug are well known, but it has been found difficult to devise a method of oral administration which can be relied upon to give a good picture of the gall-bladder. A report on the clinical use of oral tetragnost gives detailed instructions for the preparation of the patient, and the author states that, provided his technique is accurately carried out, a satisfactory result can be obtained in 80 per cent. of cases. Nearly twenty pages of the report are devoted to vigantol (irradiated ergosterol). The dose recommended is from 0.5 to 1 mg. of the pure preparation (7 to 14 drops of standardized vigantol). The standardized vigantol is stated to be about twice the strength of the American viosterol, which is standardized to have an activity 100 times that of a high-class cod-liver oil. Considerable space is devoted to the question of hypervitaminosis, for apparently the popularity of vigantol in Germany has led to this condition being termed "vigantol poisoning." Messrs. Merck point out that clinical cases of poisoning by excess of ergosterol are very rare, and that there is a general agreement that all forms of irradiated ergostcrol are equally apt to cause poisoning when given in massive doses to animals. Some space is devoted to the controversy over the value of irradiated milk. Most of the authors quoted consider that the vitamin content of such milk is too low to be efficacious as a curative agent.

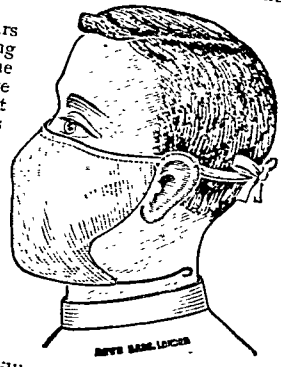
PREPARATIONS AND APPLIANCES

A SIMPLE FACE MASK FOR MIDWIFERY WORK

Dr. HOWARD E. COLLIER (Redditch) writes: The belief that many cases of puerperal sepsis result either directly or indirectly from infection from the throats, noses, etc., of those who are in attendance upon the cases and who are carriers of virulent organisms, has been growing in strength during the last few years. Therefore it has become necessary that some efficient means should be devised for protection from droplet infection. A good maternity mask should conform to the following requirements: *(a)* it should be cheap; *(b)* it should be comfortable to wear; *(c)* it *must* be efficient to prevent the passage of organisms through it; *(d)* it should be easy to sterilize.



During the last three years I have been experimenting with different masks, the essential parts of which have been a shield of jaconet mounted upon various kinds of frames. At first I used a head-phone band, later a Seymour Jones spectacle frame, and now, on the advice of the makers (Messrs. Down Bros., London) the jaconet shield has been attached to a strip of flexible aluminium. The mask has been submitted to Dr. Leonard Colebrook of the inoculation department of St. Mary's Hospital, to Professor Miles Phillips of Sheffield, and to Professor Beckwith Whitehouse of Birmingham. As the result of their advice and criticism the present mask is submitted for general use.

It consists of a piece of jaconet applied to a strip of flexible aluminium, to the ends of which tapes are attached, which are tied round the back of the head. The strip is moulded by the wearer to the shape of his nose and face. To the lower part of the jaconet is attached a light, open, metal neck-spring, which serves to prevent the mask from flapping forward when the wearer bends forward. The mask can be sterilized by simple washing in a strong antiseptic solution. It is germ-proof, does not fog the glasses, can be worn in any place, and is reasonably comfortable to wear. The price is 1s. I feel sure that its general use by doctors and midwives would materially lessen the incidence of puerperal sepsis.

NEMBUTAL

Nembutal "844" (Messrs. Spicer and Co., Ltd.) is a barbituric acid derivative with the constitution of sodium ethyl methyl-butyl barbiturate. The barbituric acid derivatives have been subjected to intensive research in recent years with the purpose of finding some compound suitable for use as a sedative for preliminary medication in general, spinal, or local anaesthesia. Comparative analysis of the modes of action of members of this series has revealed interesting differences in their pharmacological actions. Some derivatives are eliminated slowly from the body and produce a prolonged action, whereas others are eliminated more rapidly and produce a shorter action. Considerable variations have also been found in the therapeutic ratios (effective narcotic dose: fatal dose). Nembutal is a powerful hypnotic, but it is of the short-acting class, for recovery occurs in four hours; it is therefore particularly suitable for preliminary medication in anaesthesia. Like many others of the more complex barbiturates it hydrolyses on keeping in aqueous solution, and solutions for intravenous injection must be prepared shortly before use. The makers direct that it should be dissolved in sterile distilled water, and, presumably, it is undesirable to boil the solution. The drug has been used with success in a large number of surgical cases. The makers emphasize the necessity of following exactly the directions regarding dosage, rate of injection, etc. The drug can be given either intravenously or by rectal injection as a preliminary medication in anaesthesia.

DESICCATED STOMACH

Gaster siccata (B.D.H.) is prepared from selected stomachs of animals certified healthy. The preparation is intended for use in pernicious anaemia. Several authors have reported in these columns and elsewhere that treatment with dried stomach produces results in pernicious anaemia equal to those produced by liver treatment. The preparation under notice is an insoluble powder, which can be given suspended in milk. The dose recommended is from to 30 grams.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

250TH ANNIVERSARY

Centenary celebrations are much in the air at present, and it has become the fashion to hold minor commemorations at the intervening fifty-year periods. It is natural, therefore, that the Royal College of Physicians of Edinburgh should celebrate on St. Andrew's Day of this year the 250th anniversary of its foundation on November 29th, 1681.

In 1505 James IV confirmed a charter incorporating the Guild of Surgeons and Barbers in Edinburgh, and out of this, the first medical corporation in Scotland, the Royal College of Surgeons developed. James VI of Scotland and I of England granted in 1599 a charter to Mr. Peter Lowe and Mr. Robert Hamilton in the West of Scotland to test the skill of any persons practising surgery in that part of the country, and from this sprang the Royal Faculty of Physicians and Surgeons in Glasgow. In 1621 the same king signed an order to the Scottish Parliament to erect a College of Physicians in Scotland which would function from Edinburgh. This project, however, was strongly opposed by the bishops, the Corporation of Surgeons of Edinburgh, and the universities, which then had some notion of establishing medical schools of their own. The plan for a College of Physicians, therefore, did not mature till 1681, when, through the good offices of Sir Charles Scarborough with King Charles II and Prince James, a charter was granted to Sir Robert Sibbald and twenty associates, empowering them to found a College of Physicians in Edinburgh. The Great Seal was affixed to this charter on November 29th, 1681, being St. Andrew's Day, and the College thereupon came into being. Under the charter the new College was empowered to draw up laws for its government, and for promoting the science of medicine, and regulating its practice within the city of Edinburgh and Leith. The College was also empowered to examine the apothecaries and test their medicines in this city, and the Fellows at once set about drawing up a *Pharmacopoeia*, which was finally published in 1699. It went through thirteen editions, and did much to standardize medicine in Scotland until the first issue of the *British Pharmacopoeia* in 1864. One of the earliest and most productive efforts of the College of Physicians developed from the idea entertained by some of its Fellows to found a regular medical school in Edinburgh. Sir Robert Sibbald and a few of his friends had already, about 1670, laid out a physic garden in the city, and induced the town council to appoint a professor of botany.

Dr. Archibald Pitcairne, one of the original Fellows of the College of Physicians, who had been professor of medicine at Leyden and the instructor of the later celebrated Boerhaave, began in 1700 to reorganize anatomical teaching at Edinburgh under the Incorporation of Surgeons, with the result that in 1720 Alexander Monro was appointed professor of this subject by the town council. In 1724 four Fellows of the College of Physicians —Dr. John Rutherford, Dr. Andrew St. Clair, Dr. Andrew Plummer, and Dr. John Innes—purchased a house for a "chemical elaboratory," and commenced to teach the various branches of medicine, being appointed professors by the town council two years later. After a professor of midwifery had been appointed in the person of Mr. Gibson, who belonged to the Incorporation of Surgeons, the Medical Faculty of Edinburgh University was complete, largely by the efforts of Fellows of the College of Physicians.

An early activity of the College of Physicians which has had far-reaching effects in medicine was the establishment of the Royal Infirmary of Edinburgh. In 1725 the College opened a subscription list to erect an infirmary for the sick poor, the College binding itself that one or more of its Fellows would attend this hospital faithfully and freely, and by August, 1729, a small hospital with six beds was established. The managers of this institution at an early meeting resolved that only Fellows of the Royal College of Physicians should in time to come act as physicians to the Infirmary. From time to time in the next two centuries when the Infirmary was in need of funds the College of Physicians came to its assistance with substantial aid.

HALL OF THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

From an early date the College of Physicians conducted examinations for the purpose of licensing persons who desired to practise as physicians within the jurisdiction of the College, and in course of time, after the passing of the Medical Act of 1858, the College of Physicians combined with the Royal College of Surgeons at Edinburgh and the Royal Faculty of Physicians and Surgeons in Glasgow to establish the Scottish triple qualification. Various other medical activities engaged the College from time to time. At its beginning the College laid the foundations of a library, to which every entrant was expected to contribute a book or books, and the library now contains well over 100,000 volumes, many of them being early books of rarity and value. A College Hall was established, which changed its site with the development of the city, and is now located in a handsome building at 9, Queen Street, Edinburgh. With the development of scientific research the College, in 1889, established a laboratory in a small house in Lauriston Lane, close to the Royal Infirmary. So fruitful was the work done here that from 1915 an annual volume of reports has been published, and a great amount of routine reporting has been carried out, the reports numbering in all about 15,000. In addition to the Royal Infirmary, many other medical institutions of Edinburgh owe their inception or their foundation in large part to Fellows of the College. Among these are the Royal Mental Hospital at Morningside, the Royal Public Dispensary, the Royal Blind Asylum, and the Royal Maternity Hospital.

British Medical Journal

SATURDAY, FEBRUARY 28th, 1931

IODINE IN RELATION TO GOITRE

The empirical use of iodine in the treatment of goitre dates from 1820, soon after the chemical isolation of iodine. The observations of Coindet at that time proved that some cases of goitre were cured by internal medication with iodine or by its application as a salve over the thyroid gland. Iodine still remains the most potent of all remedies in the treatment of parenchymatous goitre. Not all cases, however, respond to treatment with iodine; and some are made worse if the dosage is excessive. Intoxication from excessive iodine medication in cases of struma may closely simulate Graves's disease, producing rapid heart action, muscle tremor, loss of weight, and increased rate of basal metabolism. It seemed somewhat rash, therefore, of Plummer in 1922 to advocate the administration of iodine in the treatment of exophthalmic goitre; but the experience of surgeons throughout the world has confirmed the value of iodine medication, both pre-operatively in improving the patient's general condition and in reducing the operative risk, and after the operation in promoting convalescence and ensuring stabilization of the result obtained. Biochemical research showed the importance of iodine in the tissues of the thyroid gland as compared with other parts of the body structure, and culminated in Kendall's isolation of the thyroid hormone, thyroxine, which on analysis proved to contain a high proportion of iodine.

It would seem reasonable to suppose that a deficiency in iodine is a causative factor in endemic goitre, but the many observations brought forward in proof of this thesis have not found universal acceptance. Chatin studied for years the distribution of iodine in various parts of France and Switzerland, and became convinced that a deficiency of iodine was a cause of goitre and cretinism. But commissions set up by the Paris Academy, while confirming his chemical results, did not accept his conclusions as to the cause of goitre. McCarrison, as the result of observations on endemic goitre in India, was led to believe that the determining factor in the development of this condition was a toxic agent derived from the alimentary tract rather than a deficiency of iodine in water or food. A recent revival of interest in the problem is shown by the publication of careful work carried out in places where goitre is endemic. Kimball, for instance, has reported the results of exhaustive goitre surveys and water analyses in Michigan, U.S.A.; the iodine content of the water supply appeared to be inversely proportional to the incidence of goitre.

During the last few years investigations made in New Zealand, where in places goitre is endemic, led to a restatement of the hypothesis that the incidence of goitre was related inversely to the iodine content of the soil. Hercus, Benson, and Carter, in 1925, published the data obtained from the analyses of 470 soil samples, and the examination of 80,750 children. In a more intensive study by R. A. Shore and R. L. Andrew,[1] as a result of the examination of 24,000 school children, and the analysis of 300 soils in certain well-defined districts in the North Island of New Zealand, the same interesting inverse relationship is in the main established. The report is valuable in that the analysis was entirely done by one worker, while the goitre percentages were compiled by another, and the results of the work carried out independently by each observer were afterwards collated. No relation was found between the iodine content of the potable waters and the incidence of goitre. This may, of course, be due to the fact that a great deal of the water supply comes from upland surface reservoirs, largely dependent on melting snow for replenishment, and much less from deep springs, which are more likely to contain iodine. In other parts of the world—for example, in Finland[2]—evidence was obtained of a positive relation between the prevalence of goitre and a low iodine content of water, though many exceptions were found. It would indeed be surprising if a close nexus were proved, under modern conditions of exchange of foodstuffs between different districts and importation from other countries. It would be difficult to find a people living only on the produce of its own district, enabling a clean experiment to be made. The results obtained by Shore and Andrew in New Zealand are therefore the more striking in that where there is a high iodine content in the soil there is a low incidence of goitre, and where there is a low iodine content there is a high incidence of goitre.

Another method of investigation is to examine the iodine excretion rather than the iodine absorption. Under normal conditions about 60 per cent. of the iodine excretion occurs through the kidneys. It was shown by v. Fellenberg that the amount of iodine excreted by normal adults in twenty-four hours was considerably greater in districts where goitre was rare than in those in which goitre was prevalent; while Lunde[3] showed that the renal excretion of iodine of normal adults in a Norwegian goitrous district was considerably diminished where there was a large percentage of goitre among the school children of the same region. It appears, therefore, that in many places the occurrence of endemic goitre corresponds with a lack of iodine. Lack of iodine may not be the only cause of goitre, however; and McCarrison, Tanabe, and, more recently, Hellwig,[4] have brought forward evidence from animal experiments that the positive factor in the causation of goitre is the high calcium content of the drinking water. This may act by interfering with the absorption of iodine, even if the latter be present in otherwise sufficient amounts.

While the question of the iodine content of the environment in relation to the prevalence of goitre is

[1] Goitre in School Children. Report of the Departments of Health and Scientific and Industrial Research. Wellington. 1929.
[2] *British Medical Journal*, 1929, ii, 62.
[3] Lunde: *Klin. Woch.*, 1930, ix, 865.
[4] Hellwig: Ibid., 1930, ix, 1913.

thus still open, it may fairly be presumed that a gland which contains such a relatively large amount of iodine must have an adequate supply of iodine in order to continue to function normally. Attempts to increase the amount of iodine ingested by using iodized salt have apparently lessened the goitre incidence in school children in districts of the United States of America and in New Zealand. Since sea-fish contain a considerable amount of iodine, the addition of sea-fish to the diet has also been advocated. Many workers have published their views and observations on the problem of the relation of iodine to the causation of goitre. There is, at present, no general agreement; but the issues are becoming clearer, and it is to be expected that the work being done in various parts of the world may lead to a conclusion that will offer a convincing solution to the problem.

MEDICAL EDUCATION IN WALES

The history of medical education in Wales, though relatively short, has been full of incident, but there seems every prospect that the Welsh National School of Medicine will soon be in a position, if it is not actually so at present, to forget as much of its past as it desires to do, and to concentrate on the future. As long ago as the nineties the pre-clinical subjects were taught at Cardiff in departments of the University College of South Wales and Monmouthshire, the students proceeding later to London and other centres for their clinical training. But when the University of Wales was founded it was decided to provide a complete medical education in Wales, and a School of Medicine was established under the dual control of the University and the College at Cardiff.

The Welsh people have a strongly developed national sense, and those best able to appreciate the position have always been convinced that Wales would eventually produce a medical school worthy of her people. But the birth pangs have been severe. From the first it was clear that the proposed dual control was too much for any young institution to bear. Cardiff College was reluctant to relinquish the control of the new school which it had done so much to develop, and the rest of Wales was equally insistent that the new Welsh National School of Medicine should be the property of Wales and not of any one Welsh city. At one time it seemed even possible that the project would fail altogether as the result of internal dissension; but happily a complete breakdown has been avoided, and there seems every likelihood that peace has at last been attained. The University of Wales, the University College of South Wales and Monmouthshire, and the Welsh National School of Medicine, have been granted charters and supplemental charters, in which the position has been defined, it may be hoped, to the satisfaction of all parties. The Welsh National School of Medicine now becomes an independent constituent school of the University, but the departments of the pre-clinical year will be under a joint academic committee of the School and College. The interest of the College in the departments which it had established long before the complete school was contemplated is thus preserved. Further, it has been agreed that should the Federal University of Wales at any time become broken up, the School of Medicine will form part of a new University of South Wales and Monmouthshire at Cardiff.

Whether the possibility thus foreshadowed has any stronger basis than an expression of civic patriotism only those on the spot can tell. But, whatever the future developments may be, it is to be sincerely hoped that the School of Medicine will now enter upon a period of serenity, untroubled by political discussions. The effect on teachers and students alike of such a state of affairs as has existed at Cardiff is incalculably bad. Academic bodies may differ hotly over academic matters with much benefit to themselves and their pupils, but when a scholastic institution becomes a bone of contention, and the contest is declared open to all, the primary object of its existence inevitably suffers. That the Welsh School of Medicine has survived its early troubles is proof of its vitality; if it is allowed to mature unhampered it will assuredly take a worthy place among the medical schools of Great Britain.

PHARMACOLOGICAL LABORATORIES OF THE PHARMACEUTICAL SOCIETY

The Pharmacological Laboratories of the Pharmaceutical Society of Great Britain have now completed five years of work, and we would like to take this opportunity of expressing the indebtedness of the medical profession, both to the society that organized and pays for this laboratory, and to those who have carried on its work in such a successful manner. The purpose of the laboratory is to provide facilities open to all who desire to have drugs standardized biologically, or to obtain an estimate of the vitamin content of foods or drugs. In addition to this routine work the laboratory has carried out valuable research on subjects of great practical importance—such as variations in toxicity of drugs, factors influencing the stability of drugs, and methods of biological standardization. During the nineteenth century the manufacture of drugs passed from the hands of retailers into those of the manufacturing chemist, and at the same time the galenicals began to be replaced to a large extent by synthetic drugs whose purity could be measured by simple chemical tests. The troubles experienced by previous generations of physicians in obtaining drugs of adequate purity appeared to be approaching solution towards the end of last century, but just about that time the progress of medicine introduced a series of new problems. The introduction of such therapeutic agents as antitoxic serums, complex organic compounds used in chemotherapy, endocrine products, and vitamins, raised new difficulties, because for all these substances chemical tests were inadequate to measure either therapeutic activity or toxicity, and hence the need for biological standardization arose. The problem was somewhat similar in form to that which faced the profession in the times of the Tudors, though scientific progress had made it more complex. In those days the physicians

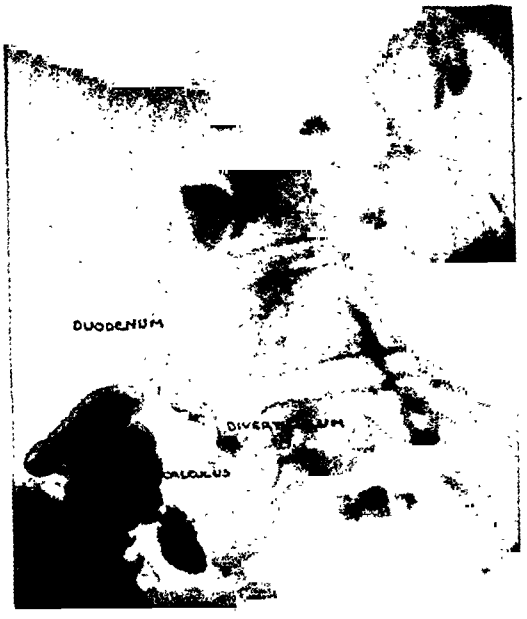


FIG. 1.—Pedunculated diverticulum at the convex side of the third part of the duodenum, with shadow of calculus in close relation to it.

FIG. 2.—Diverticulum fully filled, is masking calculus which can be seen on Fig. 1. Note dilatation of duodenum, indicating some degree of ileus.

FIG. 3.—Small diverticulum of the ileum.

FIG. 4.—Small diverticulum of appendix, with multiple diverticula of the colon.

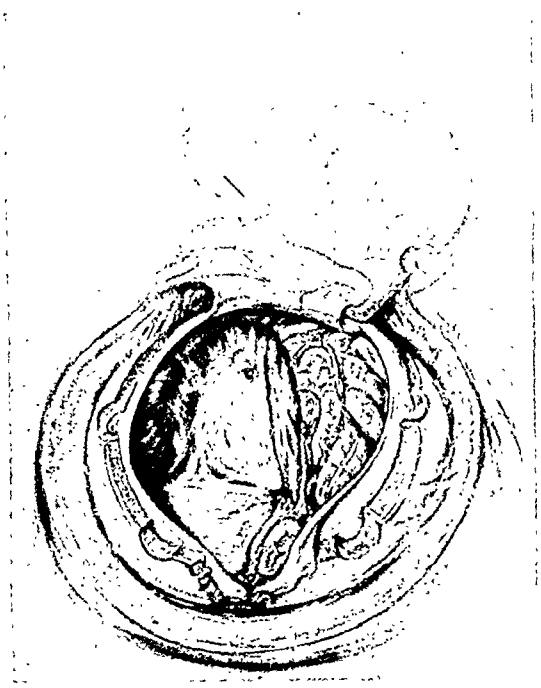

FIG. 1.—Case of multiform spongioblastoma of the left occipital lobe. The lobe has been removed, exposing tentorium and falx.

FIG. 2.—Antero-lateral view of a ventriculogram showing symmetrical ventricular dilatation with the shadows of the calcified choroid plexus on either side.

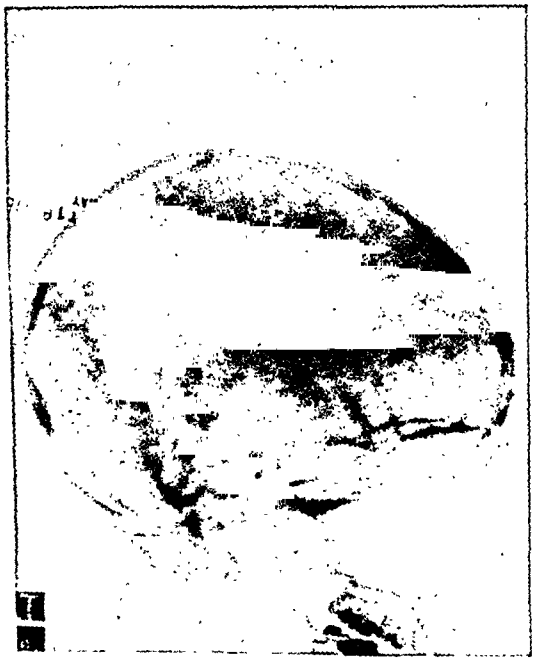

FIG. 3.—Case of oligodendroglioma of the right frontal lobe. Note the granular calcification in the substance of the tumour.

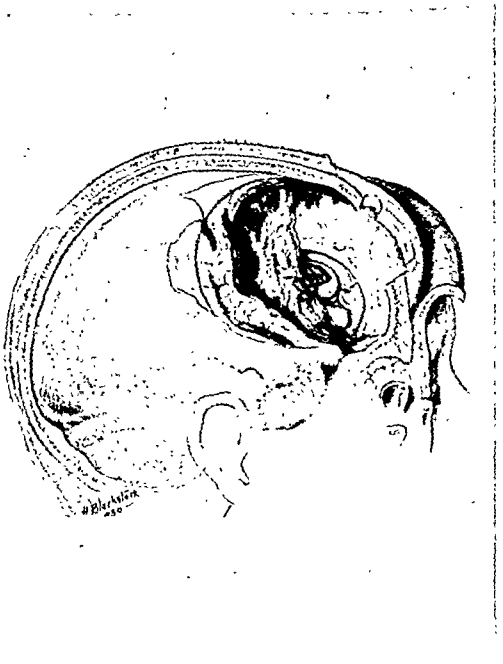

FIG. 4.—A schematized antero-posterior section of the skull to show the amount of removal of cerebral tissue in the case illustrated in Fig. 3. The anterior portion of the falx is exposed.

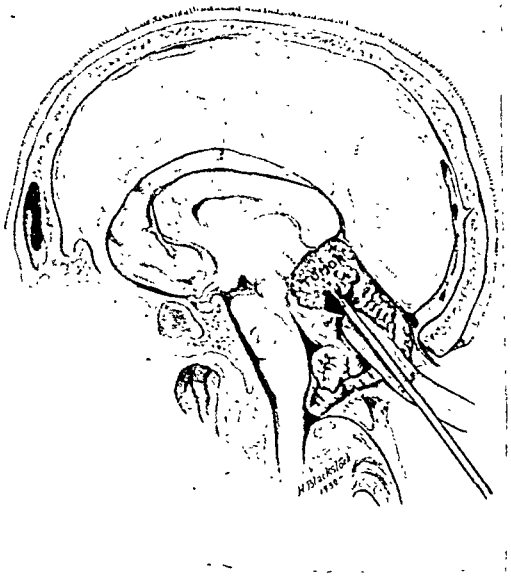

FIG. 5.—Schematic drawing to show the situation of the polar spongioblastoma removed by suction.

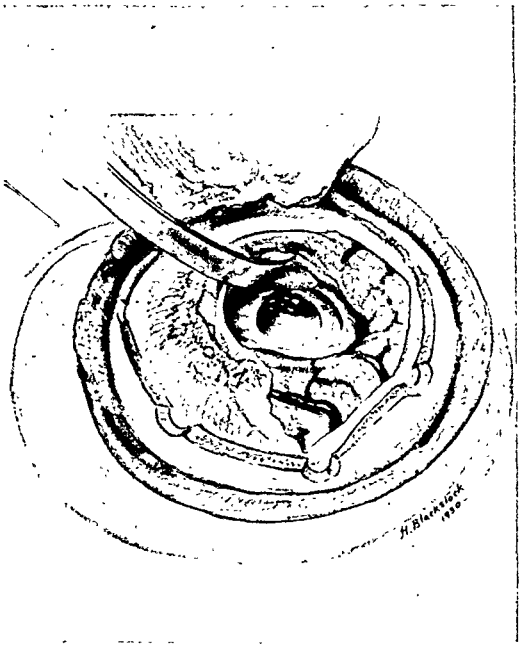

FIG. 6.—The roof has been removed from a cyst in the temporo-parietal region. The edges of the cyst have fallen inwards. The neoplasm itself at the bottom of the cyst is indicated as being dark just beyond the retractor. The walls of the cyst are made up of cerebral tissue and are not neoplastic. The dura was densely adherent to the surface of the brain.

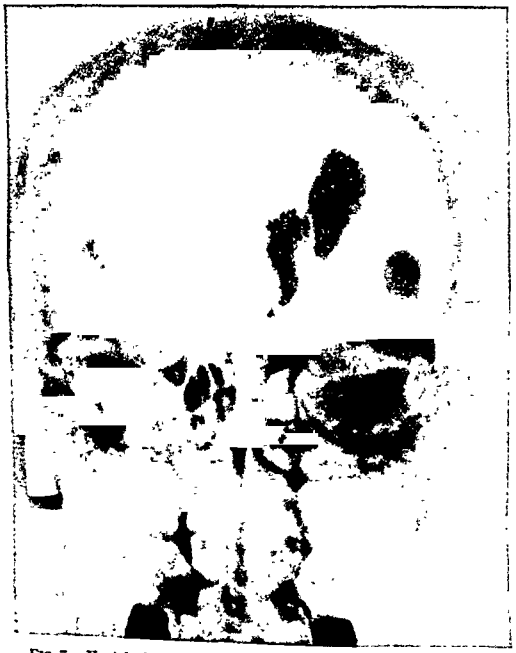

FIG. 7.—Ventriculogram taken with the brow up showing both anterior horns of the third ventricle pushed across to the right by a meningeal fibroblastoma in the posterior portion of the left frontal lobe.

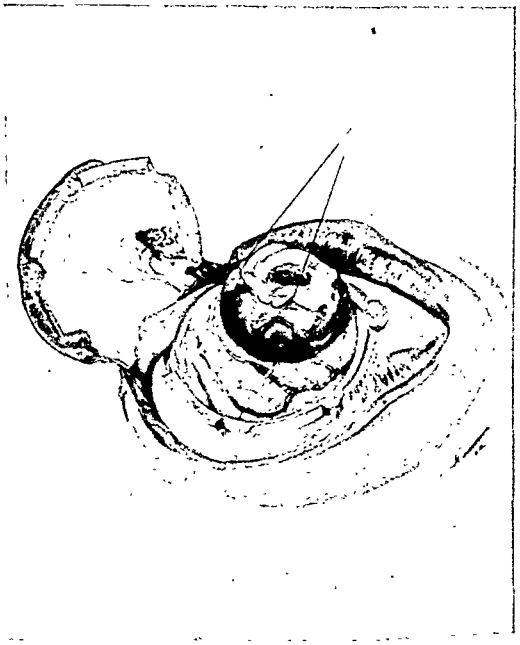

FIG. 8.—Meningeal fibroblastoma being removed from the left frontal region.

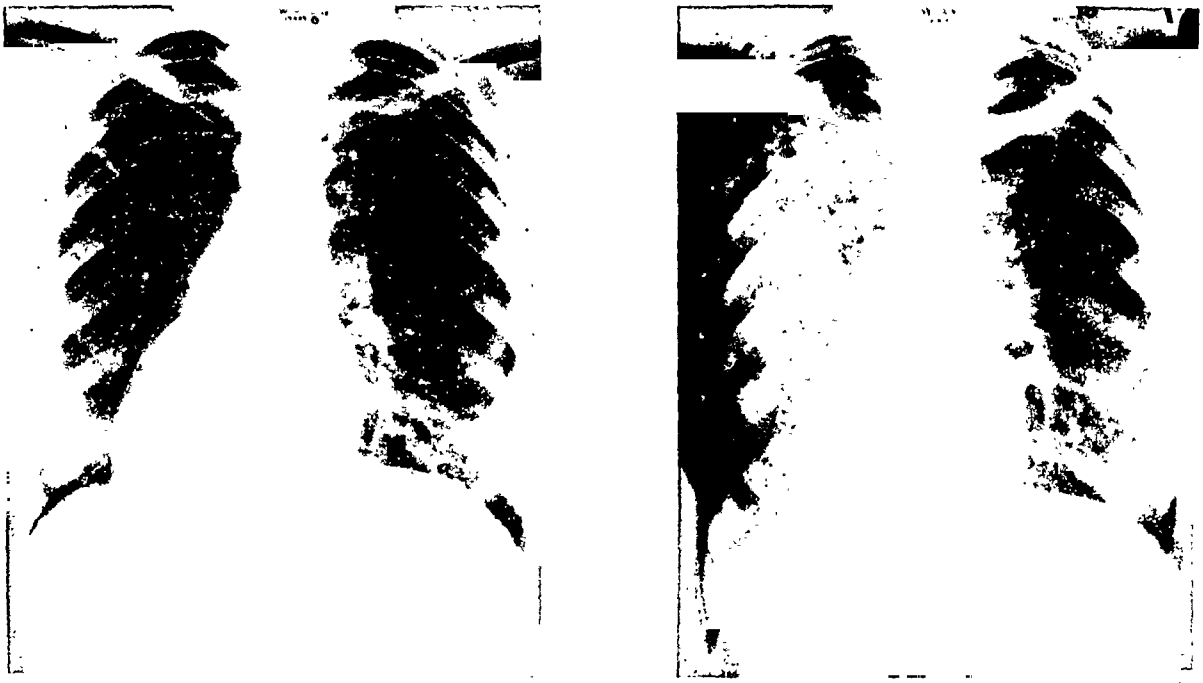

FIG. 1.—Female, 16½, October, 1928. Right: calcified lymph node above 6th post. rib; faint inverted salients below neck of 2nd post. rib. Left: irregular soft clouding in post. 2nd, 3rd, and 4th i.s. FIG. 2.—May, 1930: shows increased lesion. History: December, 192[illegible] below the neck of 2nd rib (r. and l.)—the only parenchymal lesion. February, 1928; lesion on left reached 3rd and 4th post. i.s.; a few rales only. May-October, 1928, patient ambulant in sanatorium; gained 5½ lb., averaged 94 per cent. normal wgt.; [illegible]uary, 1929; slight retrogression. May, 1930; definite rales; pulse and temperature normal. No symptoms.

Male, November, 1927, aged 11. X-ray showed calcified nodules and nodes; same picture March, 1928. September, 1928, TBN was + to 0·01 mg.; temperature 98.6°; wgt. 90 per cent.; no symptoms. October 1, cough; sputum ½ oz.; five specimens negative. FIG. 3.—13/10/28. Right; 2 calcified nodules on 8th and 9th ribs near tip of 5th rib; with four associated nodal calcifications in hilum in 7th and 8th i.s. and on 8th rib; fresh, soft, unequal density in 5th and 6th post. i.s. Oblique films showed this as situated on post. chest wall. The small density in 5th post. i.s. close to spine, is due to a vessel. Left: granular nodal calcification in hilum at 7th post. i.s. Symptoms: morning cough only; patient in bed at home except for dispensary visits. FIG. 4.—increased lesion with central excavation despite gain in wgt., absence of fatigue and fever, and decrease in cough; sputum negative; wgt. 97 per cent.; rest in bed continued. January, 1929, retrogression definitely begun. June, 1929, still improving.

of London were willing, nay even determined, to supervise the activity of the apothecaries and to ensure a supply of reliable drugs, and there was much controversy between the two professions. First, the College of Physicians and then the Society of Apothecaries was given power to inspect drugs. This privilege was associated with the right of entry for the purpose of inspection, and the right to destroy defective medicines. No such eagerness was displayed by these corporations in meeting the drug problems of the twentieth century, possibly because the organization of facilities for biological standardization of drugs involved heavy expense. A solution of the problem was sought by various means. Government action provided for the standardization of various important drugs such as organic arsenicals, many of the larger drug firms instituted laboratories in which they tested their own products, and a certain amount of work was done in university laboratories. There was, however, an obvious need for a public institute in which an authoritative and impartial estimate of the biological activity of preparations could be obtained. The Pharmaceutical Society is to be congratulated on the public spirit which it has shown in providing and maintaining such an institution.

NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL

In the great development of medical education during the last fifty years, one of the most remarkable changes is the transformation of the medical curriculum and teaching bodies that has occurred in the United States of America. This should be ascribed, first, to the influence of Sir William Osler and the Johns Hopkins Hospital, which has been carried on until the present day by Professor W. H. Welch; and secondly, to Mr. Abraham Flexner's report to the Carnegie Foundation on Medical Education in the United States and Canada, which, acting more rapidly and dramatically, led to the elimination of a number of proprietary schools of medicine, so that now the schools listed by the American Medical Association (which has taken an active part in the good work) are almost all of the "A" category. The instruction in the proprietary schools was, in some instances, very inadequate; there is the notable, and extreme, example of Walter Reed of yellow fever fame, who obtained an M.D. at the University of Virginia in 1869, after one year's medical work. Post-graduate teaching was therefore urgently needed, and with this object many recent M.D.'s flocked to Europe, and especially to Vienna. The desirability of providing these facilities in New York was recognized in 1875, when eight of the teachers in the Faculty of Medicine in New York University, under the leadership of the late Dr. D. B. St. John Roosa, established a post-graduate department in the University. After six years they realized, as many have since done, that under-graduate and post-graduate teaching cannot be successfully combined, and, as the university refused to provide a separate building for the graduates, they took the serious step of resigning their appointments there in order to organize the New York Post-Graduate School. This was in 1882, when post-graduate teaching in London was being advocated, and developed, in a small way, by Sir Jonathan Hutchinson, Sir William Broadbent, and others. It is natural to compare progress in this project in the two great cities, and satisfactory that at the present time both are entering upon a period of great expansion. In London the Government is helping in the establishment of a school and hospital, which, it is hoped, will be worthy of the centre of the Empire, and in New York the Post-Graduate Medical School and Hospital has just been incorporated with Columbia University. The President of Columbia, Dr. Nicholas Murray Butler, who announced this important event at the annual dinner of the New York Post-Graduate Medical School and Hospital on January 31st, gave the union his blessing, and joined the board of directors of the New York Post-Graduate School. Dr. Chace, the president of the school and chairman of the dinner, and Dr. Willard C. Rappleye, the new dean of the school, and lately the director of studies of the Commission of Education, also spoke in terms of gratification. Thus, starting as a secession from a university medical school, and after forty-eight years of independent existence, during which it has improved the education of 27,324 medical men, the post-graduate school now again becomes part of a university.

AN INDEX TO PHYSIOLOGICAL PROGRESS

We welcome the recently published Subject Index to the first sixty volumes of the *Journal of Physiology*,[1] not only as a record of the progress of physiology in this country, but also as a joint memorial to Sir Michael Foster, the virtual founder of that journal, and to one of the greatest of all scientific editors, the late Professor Langley. Those who take the trouble to look through this comprehensive work (prepared by Dr. J. G. Priestley) will be rewarded with a view of the onward march of a science which, since the inception of the *Journal of Physiology*, has been, in a sense, a peculiarly English study. But careful inspection of the subject index, devoid as its pages are of the glamour of distinguishing and distinguished personality, does something more: it reveals the width of interest of our laboratories, and a gradual change in emphasis. Above all, the volume testifies in a striking manner to the catholicity of taste, acumen, critical judgement, and faith of J. N. Langley. It is as much as anything his memorial—a lasting record of a life spent in the service of physiology. The reader who passes in review before his mind's eye the work catalogued in these 200 pages will see reflected therein the genius of the national character. Here is to be found in briefest epitome the tale of attack after attack on the great physiological systems—for example, fourteen and a half columns devoted to striated muscle, fourteen columns to heart, ten columns to respiration, six columns to the nervous system in general, and four columns to the vagus alone. We may not be an imaginative race, but when a problem offers well-nigh insuperable difficulties there is no hesitation. Our men of science do not have to whet their appetite for research on trumpery *hors d'oeuvres*. Long may this interest in the great basal problems, with its accompaniment of hard and often rather dull work, characterize the British race. The *Journal of Physiology* is a noble record of steady work well done.

ACROCYANOSIS

Acrocyanosis, the subject of an interesting and exhaustive study by Dr. Fernand Layani,[1] is a term seldom used in English medicine, and it is curious to remark how insular most countries are in their choice of medical delicacies. Acrocyanosis means persistent blueness of the extremities, and at first sight it might be thought that such a condition was very common in certain circumstances, and but little removed from the physiological state. The pathological nature of the manifestation is to be inferred, however, when it is understood that the blueness of the hands and feet must be accompanied by coldness and by secretion from the sweat glands. Endocrine disturbances, and a high venous pressure, measured by methods current in France, have also come to be associated with the rather imperfectly defined syndrome. Hands afflicted with acrocyanosis are blue, cold, and damp; they may in certain cases be oedematous, and, more rarely, the site of trophic changes. This combination is unusual. We are accustomed, in the course of the daily round of greetings, to normal hands, to bluish hands, to cold dry hands, and to warm moist hands, but we should be at once disagreeably impressed by cold and wet hands politely tendered, even if they were not blatantly blue. Had not Uriah Heep such clammy members? There is no possibility of confusing the syndrome with Raynaud's disease, in which the cyanosis is spasmodic and localized, in some cases to a finger-tip. It is desirable to point out at once that Dr. Layani has not succeeded in elucidating the cause of the syndrome. Having made this clear we may proceed to discuss the symptoms on what may be loosely termed an actuarial basis. The syndrome was born as recently as 1896, at a congress of alienists and neurologists held at Nancy, which a few years ago attained notoriety as the birthplace of a therapeutic cult which has already passed into obscurity. Since that date acrocyanosis has been the subject of much literature and research, principally in France. Its spectacular nature rivalled that of Raynaud's disease, and it became embellished with many sensational and romantic observations, in a similar way to Raynaud's disease, which has of late years been shorn of the fantastic, and ranged among the diseases of known pathology. The symptoms of acrocyanosis seem to lend themselves to "arm-chair analysis." We know that the skin of normal hands may be blue at temperatures between extreme cold and extreme heat, and the few skin temperatures mentioned by Layani seem to fall in this part of the cutaneous thermometric scale, though in some passages he stresses the extreme coldness of the skin and in others the varying degrees of cyanosis; before proceeding further we ought to state in each supposed case of the disease the temperature and cyanotic tint (on the recognized cutaneous colour scale), and determine their departure, if any, from normal. The remaining symptom, sweating of the hands and feet, is by no means infrequent, and we do not know how far it denotes a pathological state; that it might occur in a certain number of people whose skin temperatures favoured cyanotic tints seems likely, and, before deciding that such a combination makes up a syndrome, we ought to be in a position to say whether it occurs more often in a large group of people examined than the laws of probability allow. If such an analysis were favourable to the reality of the syndrome, then the methods so successful in the case of Raynaud's disease would probably explain its nature.

ROUTINE ANAESTHESIA IN MIDWIFERY

The desirability of giving light anaesthesia in childbirth in hospitals under the London County Council's control has been considered by the Central Public Health Committee. It will be remembered that the general conclusion of the Departmental Committee on Maternal Mortality and Morbidity was that light obstetrical anaesthesia by the intermittent method might with advantage be administered to suitable cases of normal labour, particularly to primiparae, to a greater extent than has generally been the practice hitherto. In the maternity wards of twenty-three hospitals now transferred to the London County Council 7,454 patients were delivered in 1929, and of these 877 received either sedative, analgesic, or anaesthetic; 382 received a sedative only, 412 an analgesic only, and 83 (mostly abnormal cases) a general anaesthetic. At five hospitals light anaesthesia was given to normal patients (mainly primiparae) in a few cases. At one hospital half the patients received analgesics, but in most hospitals only a small proportion had this form of relief. The Central Public Health Committee puts forward certain considerations in connexion with the proposed extended use of anaesthesia. Many medical superintendents, it states, hesitate to encourage a practice which they believe delays labour, increases the necessity for interference, and in other ways tends to augment the risks to mother and child which they are working to diminish. It is also pointed out that medical opinion is definitely against the administration of any form of general anaesthesia by nurses, except under the direct supervision of a doctor. Confinements occur at any hour of the day or night and are of unpredictable length, and therefore the interruption of a medical officer's routine would be out of all proportion to the time actually spent in the labour room, and would gravely interfere with other duties. In the Council's hospitals all normal labours are attended by midwives only, and if the presence of a medical officer is required on such occasions the question at once arises whether the hospital medical staff is large enough to permit of this. Further, an unknown factor in estimating the degree of insufficiency of medical staff for the purpose is the number of women who would accept anaesthesia if offered. There is said to be considerable prejudice against it in some quarters where its use has never been possible hitherto; but, judging from the numbers of women who demand this relief when they are in a position to afford it, those asking for it in the Council's hospitals would ultimately be very numerous, probably about 90 per cent. of the total. Another consideration is that the administration or supervision of obstetrical anaesthesia is not a particularly interesting or valuable experience to the young medical practitioner, and if such anaesthesia were offered to patients confined in the Council's hospital maternity units, it is essential that the duty of administration should be carried out by a rota of the medical staff, to be arranged from week to week. The com-

mittee feels, however, that the principle of providing facilities, where practicable, in the Council's hospital maternity units for the giving of light anaesthesia in normal cases of childbirth is one which, having regard to modern opinion and practice, should be conceded, at any rate for an experimental period, subject to review in the light of experience. On the question of practicability, it is stated not to be possible, in the ensuing financial year, to make the necessary arrangements in more than a limited number (about six) of the hospitals with maternity units. The result of the experiment in these hospitals will be considered after about six months' working.

OSLER'S DISEASE AND EPONYMS

Last year Dr. Hyman I. Goldstein[1] published an exhaustive bibliographical account of "Hereditary epistaxis: with and without hereditary (familial) multiple haemorrhagic telangiectasia (Osler's disease)," and concluded that there are probably a total of sixty-five families and about three hundred and fifty individuals suffering from epistaxis with hereditary telangiectasia. He suggested further that cases of familial haematuria, haemorrhagic nephritis, haemoptysis, gastrostaxis, intestinal and gastric haemorrhage, and some of the so-called essential idiopathic haemorrhages are probably different forms of this disease. As a source of reference to the history of epistaxis during the last three centuries, and especially during the last hundred years, this is a very valuable contribution. Doubts may arise about the wisdom of drawing the other diseases into the net of hereditary multiple telangiectasis, to which Sir William Osler in 1907, and Dr. Parkes Weber, both then and often since, have specially drawn attention in this country. The use of eponyms, such as "Osler's disease," is also open to criticism; they have their advantages by avoiding definitions which may subsequently prove to be erroneous, and also by economizing time when the descriptive name is lengthy, as in the case of the condition Dr. Hyman Goldstein discusses, though this argument is somewhat undermined by his quotation of "Rendu-Osler-Weber's disease." On the other hand, eponyms, though attractive to medical historians and hero-worshippers, are a sore trial to the student; they may be very confusing when the name of the same distinguished clinician is applied to more than one condition, such as that of Paget (osteitis deformans; "eczema" of the nipple), von Recklinghausen (multiple neurofibromatosis; osteitis fibrosa cystica), and Osler (erythraemia or Vaquez-Osler's disease, and multiple hereditary telangiectases); or when two Wilsons have their names thus perpetuated (Erasmus Wilson's exfoliative dermatitis, and S. A. K. Wilson's progressive lenticular degeneration). It is therefore fortunate that eponyms, as, indeed, some of those just mentioned, tend to drop out of current literature, as is shown by a glance at the heading "Disease" in Dorland's *Medical Dictionary*. Moreover, there is not any rigid custom in the apportioning of eponyms; the name is not always that of the first observer, for it may be credited (and there is some justification for so doing) to the describer who provides the fullest account of a disease which, though previously recorded, had almost escaped recognition. Different countries may apply the names of their own medical leaders to the same disease: an outstanding example of this is Graves's, Parry's, Basedow's, Flajani's disease, or exophthalmic goitre. Leading cases in legal procedure are necessarily known by the names of the parties concerned, but there is not the same reason for the eponymic practice in medicine.

A NEW INSTITUTE OF MEDICAL HISTORY

Professor Paul Diepgen, in the *Klinische Wochenschrift* (February 7th, p. 269), gives an interesting account of the new Institut für Geschichte der Medizin und der Naturwissenschaften in Berlin. Conveniently situated in the centre of the town, near the university, the libraries, and the clinics, it occupies the second floor of a large building, and contains a lecture theatre, a library with accommodation for 20,000 books, research and reading rooms, a kitchen, a spare room for visitors, and a safe for its most treasured possessions. The staff consists of a director, two subdirectors, four assistants, two secretaries, and a librarian. The aims of the institute are praiseworthy. In addition to special courses in medical history and bibliography, lectures have been arranged for students and practitioners on "living history of medicine," illustrated by cases selected from general practice: how, for example, a case of puerperal fever was treated by Hippocrates, and how it is treated to-day, the meaning of the difference in treatment, and how the problem of puerperal fever has remained essentially the same. In the evenings there are lectures of a lighter kind, intended for busy practitioners, to serve as respite from the serious affairs of life. The institute is to remain open from early morning until late at night, including week-ends.

SIR CHARLES HASTINGS LECTURE

The fourth of the series of Sir Charles Hastings Lectures, inaugurated by the British Medical Association for the purpose of offering to the public information by the highest authorities on matters of general public health interest, will be delivered in the Great Hall of the Association's House in London on Friday, March 13th, at 8 p.m. This year's lecturer is Dr. Edward Mellanby, F.R.S., professor of pharmacology in the University of Sheffield, and his subject will be "Diet and Health." The chair will be taken by Lord Moynihan of Leeds, President of the Royal College of Surgeons of England, and after the lecture relevant questions in writing will be invited. Admission is free, by tickets obtainable on application to the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by ticket-holders by 7.50 p.m. will be available for other members of the public.

The annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on Tuesday, March 17th, at 5 p.m.

We regret to announce the death, on February 21st at Folkestone, of Dr. Cyril Ogle, consulting physician to St. George's Hospital.

ATMOSPHERIC POLLUTION AND FOGS

BY

PROFESSOR J. S. HALDANE, C.H., M.D., F.R.S.

The interesting account in the *British Medical Journal* of February 14th (p. 277) of the investigations by Professors Nolf, Firket, and Leeuwen, into the causes of the Meuse fog disaster in December has prompted me to write this article. It appears that the disaster was caused by the ordinary products of combustion from the chimneys of factories and other industrial undertakings scattered about in the sparsely populated neighbourhood of the district near Liége where the disaster occurred; and the possibility of a similar disaster happening in this country is a matter of great public interest. If a similar concentration of similar products of combustion were to occur in the air of any large town in this country, the deaths would be numbered not in tens but in thousands.

From the symptoms described, and the clinical and post-mortem evidence, the effects on men and animals were due mainly, if not entirely, to the sulphur acids (sulphuric and sulphurous acids) in the products of combustion, owing to the irritant action of these substances on the air passages. Symptoms and signs of nasal inflammation, laryngitis, and bronchitis were evident, but not of pneumonia. The sulphuric acid is present in the air as minute liquid droplets of dilute sulphuric acid condensed on solid nuclei, while the sulphurous acid is present as gas. It was suggested that hydrofluoric acid might also have been present in very small quantities, but my own experiments with this substance during the war did not seem to indicate that, in spite of its striking action on glass, it is more dangerous as a constituent of air than other mineral acids.

The dangers arising from atmospheric pollution by products of combustion were discussed in the inquiry in December last, before the Electricity Commissioners, as to the proposed very large electrical generating station (now sanctioned by them) to be erected at Fulham. Evidence as to possible risks to public health and safety was given, on behalf of the London County Council, by Dr. J. S. Owens, Dr. Daley, and myself, and as to possible damage to buildings by Sir Frank Baines. Assuming from the newspaper evidence that the fog disaster near Liége was due to ordinary products of combustion, I myself discussed the question why it is that though the products of combustion emitted per acre of ground are probably greater in amount in London than in the Liége district, nothing comparable to what occurred in the latter district last December, or in the winter of 1911, has ever occurred in London. I pointed out that in a town a very large amount of heat is emitted at or near the ground level. This warms the air sufficiently to cause convection currents which carry it upwards, and at the same time to evaporate to a considerable extent the liquid particles which constitute fog. These particles are evaporated to a much greater extent inside buildings, though acid nuclei still remain, and make the air inside just as irritating as that outside. Many of the Liége victims had never been outside at all.

The consequence of the products of combustion being carried upwards over a town is that, instead of their becoming concentrated near the ground level, and a fog being correspondingly more opaque there, they are distributed through a layer many hundreds of feet high, and a "black" overhead fog results, in place of a stifling fog at the breathing level, as near Liége. There, owing to the absence of the warming effect produced by inhabited houses, the products of combustion accumulated down below with disastrous results. It is now a common experience of motorists and others that though it is darker in a town than outside it, the air is much less opaque during a fog. In the town of Liége itself there was no trouble from breathing the fog.

Dark overhead fogs are now much more common in London and other large towns than the more opaque, equally dark, and also more irritating fogs which prevailed last century. I think that there can be no doubt that the reason for this is the immensely increased use of gas for heating and cooking, particularly among the working classes, who have to study economy. Gas supplies heat with hardly any emission of sulphurous fumes, and none whatever of smoke. The sulphur naturally present in gas is nearly all in the form of sulphuretted hydrogen, and every trace of this impurity must, by law, be removed from the gas, the public gas examiners appointed by local authorities seeing that this regulation is most strictly complied with, in accordance with the methods specified by the Gas Referees. Although only a very small proportion of the energy liberated as heat in a large town is distributed as electricity, the electrical undertakings have hitherto taken no share in improving the atmosphere, since all the sulphur in the coal burnt at the generating stations goes into the atmosphere, along with a good deal of smoke. If the system of combustion and purification adopted at the new large generating stations at Battersea and Fulham is made really effective, and the present smaller stations throughout London are abolished, it will be no longer possible to level this reproach against electrical supply undertakings.

In their decision, which was communicated to the newspapers, as well as to others concerned, about a fortnight ago, the Commissioners have not specified any definite standard of purification, beyond the general condition that the purification shall be the best that is "reasonably practicable," and that the Commissioners, the Board of Works, and the Minister of Health must be satisfied of this. Perhaps it was impossible, in view of the somewhat doubtful and imperfect chemical evidence available, to go further than this.

In one respect, however, the Commissioners decided in the teeth of the medical evidence submitted to them on behalf of the County Council. The scrubbing process in the scheme of purification proposed would involve cooling down the effluent gas to near the air temperature. Owing to its high percentage of carbon dioxide, this cooled gas would, in periods of air stagnation, including fog, drop at once, and with only (owing to its enormous volume) a comparatively small dilution, on a small area round the generating station. The representatives of the undertaking agreed to the necessity of the gas being sufficiently heated to make it rise high above the tops of the chimneys in still weather. The Commissioners decided, however, that it was not necessary for the effluent gas to be warm; and it appeared that the basis of this decision was a memorandum (which they quote in full) from the chief representative of another Government department. This memorandum was not brought up at the inquiry. If it had been it would have been torn to pieces in the course of cross-examination and rebutting evidence. To pour down cold and heavy gas in immense volume on the people round the station and the mouths of the furnaces would be an invitation to a great disaster. The result would probably be, for one thing, a wholesale emission of carbon monoxide owing to imperfect combustion; and hundreds of people might be poisoned in consequence. The County Council has taken, or is taking, energetic steps to bring the true facts of the case before the bodies which will be concerned in guarding the public interest in connexion with the new generating stations; but it is perhaps well that,

through the columns of the *Journal*, the medical public should also know how matters stand.

It is evident that the importance of properly purifying the effluent gases from electrical generating stations and other large similar undertakings is becoming more and more recognized. With it will also be recognized the importance of emitting the gas at a suitable temperature. With reasonable purification, and the gas emitted warm, any such disaster as that near Liége could never have occurred, nor could the extensive damage to vegetation. It is more difficult to deal with the damage to buildings and other property, through the use of ordinary coal fires, and even coke or smokeless coal fires ; but by the substitution of gas fires for ordinary fires considerable progress has been made in this direction.

One interesting historical fact which occurs to me in relation to the great improvement in connexion with the composition of London fogs is as follows. The air was formerly so very unpleasant in the House of Commons, as well as outside, during fogs, that a large fog-filter of cotton-wool was designed by Dr. Percy, who at that time superintended the ventilation. This filter was like an immense mattress, and was placed in position whenever a bad fog occurred, so that the air supplied had to pass through it. I can remember it well, but it was abolished many years ago, partly because it was no longer necessary, partly owing to danger from fire, and partly because it obstructed the ventilation, and people had begun to trouble more about germs than about chemical constituents of the air.

Recent information as to the chemical composition of the air during fogs in towns or industrial districts is extremely scanty ; but Dr. Russell made, last century, a large number of determinations of the carbon dioxide in the air at St. Bartholomew's Hospital, and found that during one of the thick fogs then prevalent the percentage rose to as much as 0.14 per cent. Allowing for the probable error of the Pettenkofer method which he used, this indicated an excess of 0.1 per cent. It seems probable that in the fog which caused the disaster near Liége the excess may have been three or four times as great. It can hardly have been more, or symptoms of carbon monoxide poisoning would have pretty certainly occurred ; and the symptoms observed were not those of poisoning by this gas.

"UNIPOLAR AIR"

EXPERIMENTAL WORK AT FRANKFORT

[FROM A CORRESPONDENT]

The effects of certain climatic conditions—such as sunlight, temperature, humidity, and barometric pressure—upon the human organism have all been more or less studied in times past, but relatively little attention has been directed to the electrical charge present on particles in the atmosphere. The subjective symptoms experienced by certain individuals before or at the time of a thunderstorm or in association with certain seasonal winds in the South of France have been attributed to possible electrical effects, and the subject must be considered as removed from the realm of mere guesswork by the recent publication[1] of some remarkable experimental results obtained over a period of ten years at the "Institute for the Physical Foundations of Medicine" of the University of Frankfort-on-Maine, directed by Professor F. Dessauer. That they are only now available for the first time is due to a fear that premature publication might cause the work to be regarded as something in the nature of a "stunt."

Put briefly, the underlying assumption is that air contains normally both positively and negatively charged particles, which fluctuate in numbers and proportion according to climatic conditions. Normal air at ordinary altitude contains usually an excess of positively charged particles, but under certain weather conditions this surplus of positive articles may give place to an excess of negatively charged particles. The particles are roughly of two types: what are termed "light" particles, gaseous ions for the most part, and "heavy" particles, consisting of dust and water vapour. The experiments at Frankfort have been concerned with the effects on the body of air containing excess of particles of only one electrical sign. The production of ionized air with a positive or negative charge has been obtained in various ways, including the use of ultra-violet light, high-tension electrical apparatus, high-frequency apparatus, or by glowing alkalis or metals. The favourite method has been to heat a cartridge of magnesium oxide by means of a coil of platinum-iridium wire through which an electrical current is passed. Air is circulated over this and then through a grid, which is charged positively or negatively according to the "ions" it is wished to retain. After passing through the grid air containing a unipolar charge as high as 10,000 times the amount present in normal air was available for experimental purposes. The method of measuring the charge, the number of "ions" present, the loss by gaseous diffusion, electrical diffusion, and many other physical problems, have been gradually solved by various workers at the institute, and for the most part the experimental work has been carried out with "heavy" particles of medium size.

The use of this "unipolar air" for animal experiments and for the treatment of patients has been mostly employed by Dr. Happel, and he states quite frankly that many of the experiments produced negative results. Nevertheless some interesting effects were observed when patients breathed this specially prepared air, either obtaining it through a funnel or breathing in a chamber into which such air was passed. In certain cases of raised blood pressure, particularly when this was not due to renal disease, the inhalation of air with a negative charge produced definite reduction in blood pressure and alleviation of the principal subjective symptoms such as headache, tiredness, and giddiness, while, if the air breathed had a positive charge, distinctly unfavourable results and an aggravation of symptoms frequently resulted. Even where the blood pressure did not fall in cases of essential hypertension subjective symptoms were often relieved by negatively charged air, while similar symptoms were also sometimes relieved in patients with no rise in blood pressure, especially those peculiarly sensitive to climatic conditions. The usual periods of treatment were from half to one hour daily or at less frequent intervals, and the results mentioned above were carefully controlled so that patients did not know what variety of air they were breathing on any particular day. Care was also taken to make sure that the effects produced were in no way to be attributed to the minute amounts of platinum or magnesium inhaled, estimated at less than one-hundreth of a milligram in half an hour, or to any oxidation products of nitrogen. A definite amount of electrical charge appears to be "lost" in the body by this method of treatment, and it is tentatively suggested that the effects produced result from this electrical charge.

While the first ten years of work at Frankfort have been fully occupied with the scientific basis of this fascinating subject the application of results to treatment

[1] *Zehn Jahre Forschung auf dem physikalisch-medizinischen Grenzgebiet.* Edited by Professor Dr. Dessauer. Leipzig: Georg Thieme. 1931.

demands yet further experiment. The well-prepared groundwork should make this comparatively easy, and more light upon a further climatic factor may be obtained. Coming from a university of such fame and presented in such a restrained manner this work cannot be dismissed as yet another quasi-scientific method of exploiting the public with some form of electricity, and it would seem to merit serious attention.

HEALTH OF THE NAVY

REPORT FOR THE YEAR 1929

The medical staff at the Admiralty is to be congratulated on the rapidity with which the latest report[1] on the health of the Navy has been produced. A few years ago the Admiralty had considerable lee-way to make up, but the Navy is now in line with other Services, an achievement of which the Naval Medical Service can be justly proud. If the officers concerned can maintain this standard, all official reports on the health of the respective Services should in future be published about the same time. This would increase their value and render them more easily comparable.

The present report opens with remarks on the figures relating to the health of the total force, then deals in similar fashion with the Home Station, Atlantic Fleet, Mediterranean Station, America and West Indies Station, China Station, East Indies Station, Africa Station, and the Irregular List. Finally the details are given in statistical tables, following the same order. The Admiralty, having accomplished so much, might now be tempted to consider a slight reorganization of its health report. The method at present adopted separates the notes on the diseases and injuries from the statistical tables, and instructive information may therefore be overlooked. The notes might well appear before or after the tables on the respective stations, or, preferably, be consolidated in a separate section. It this were feasible, the report would become a still more interesting and valuable book of reference, and a considerable saving of money to the Government would be effected.

The statistics for 1929 show that 41,571 cases of disease and injury were entered on the sick list. The ratio per 1,000 has increased from 445.99 in 1928 to 482.03 in 1929 in a total force which shows a decrease in strength from 90,820 to 86,240 in the corresponding years. The average number of men sick daily was 1,767.40, giving a ratio per 1,000 of 20.49, an increase of 1.05 in relation to 1928.

The total number of days' sickness was 645,104, which represents an average loss of service of 7.48 days. The ratio per 1,000 of daily sick on the various stations was as follows: Irregular List, 39.31; Home Station, 24.94; Africa Station, 23.29; East Indies Station, 21.46; China Station, 19.83; America and West Indies Station, 18.74; Mediterranean Station, 17.05; and Atlantic Fleet, 13.76. The death and finally invalided rates have also increased from 2.22 and 11.41 per 1,000 in 1928 to 2.94 and 14.30 respectively in 1929.

If the admissions to hospital are examined it will be found that diseases of the respiratory system accounted for a ratio per 1,000 of 84.70; local and general injuries, 83.91; diseases of the digestive system, 76.83; venereal diseases, 73.74; diseases of the areolar tissue and skin, 45.56; and influenza, 19.26. These diseases give a total ratio per 1,000 of 384.00. The ratios for respiratory diseases, local and general injuries, and venereal diseases are comparatively high. It is reported that the total number of days lost to the Service owing to venereal diseases was 130,041, and that the average number of men sick daily was 356.25. The highest admission ratio for these diseases, 195.75, was shown by the Africa Station, and the lowest, 44.93, by the Atlantic Fleet. With the exception of pneumonia (2.07 per 1,000), pulmonary tuberculosis (2.76), dysentery (0.69), and malaria (6.22), the ratios for infectious diseases and those associated with Eastern service are negligible. It is therefore evident that the medical officers R.N. are chiefly employed in treating the ordinary diseases of everyday life. As regards the treatment of gonorrhoea, they are to be congratulated on curing sufferers from this disease in an average period of 19 days.

One of the useful purposes of an annual medical statistical report is to indicate to administrative officers the diseases and injuries which cause a high admission ratio and reduce efficiency in a force. They can then institute more effective preventive measures, if these are known, or promote further research into the causes, so that future administrative action may be taken to reduce inefficiency. The research work undertaken by personnel of the Naval Medical Service during the year under review deals with disinfectants, the vital capacity of ranks and ratings, ventilation, and the preparation of vaccines, all of which are very important subjects but not intimately connected with the everyday causes of inefficiency—namely, the diseases mentioned above.

The number of deaths was 254, of which 153, or 1.77 per 1,000, were due to disease, and 101, or 1.17 per 1,000, were due to injury. The chief causes of death were drowning, 42 (0.48 per 1,000); injuries and wounds, 22 (0.25 per 1,000); pneumonia, 21 (0.24 per 1,000); pulmonary tuberculosis, 19 (0.22 per 1,000); disease of the intestine, 15 (0.17 per 1,000); multiple injuries, 14 (0.16 per 1,000); multiple burns and scalds, 13 (0.15 per 1,000). The total number invalided out of the Service was 1,234. Among these were 29 who refused surgical operative treatment, 13 being for hernia, an unusually large figure for an operation now regarded in the Service as a simple curative measure. The chief causes of invaliding were pulmonary tuberculosis, 228, showing a ratio of 2.64 as against 1.31 in 1928; diseases of the eye, 170 (1.97 per 1,000); diseases of the ear, 132 (1.75 per 1,000); general and local injuries, 105 (1.21 per 1,000); and neurasthenia, 65 (0.75 per 1,000).

All the Services are paying special attention to dental treatment, now recognized as an important factor in preventive medicine. Throughout the year under review, the naval dental officers completed the immediate treatment required by 3,601 officers, 23,787 men, 2,725 boys, and 276 miscellaneous patients. The numbers requiring extensive operative treatment on admission to the Service increased from 25.6 per cent. in 1928 to 27 per cent. in 1929, and it must be gratifying to the Navy to find that out of 44,801 ratings dentally inspected on rejoining their home depôts 76.3 per cent., as compared with 71.5 per cent. in 1928, were not in need of immediate dental treatment.

PREVALENCE OF CEREBRO-SPINAL FEVER

On February 20th the Ministry of Health issued the following statement in regard to the prevalence of cerebro-spinal fever in England and Wales:

In view of the public notice which recent reports of cerebro-spinal (or "spotted") fever have received (particularly those relating to cases in Army and Air Force stations), it is well that it should be understood that periodical increases in the occurrence of this relatively rare disease are not unusual. Cerebro-spinal fever has been recognized and studied in this country for over sixty years, particularly when, as has sometimes been the case, it has occurred intensively in particular areas, or, as is the more general rule, when its prevalence is made up of small numbers of cases scattered through the whole country. In every year there is a certain amount of cerebro-spinal fever in the country, but in particular years or series of years its occurrence is sometimes considerably above the average. There appears to be no one outstanding cause for these increases, though a variety of different circumstances have appeared at one time or another to have influenced their occurrence.

Cerebro-spinal fever was made generally notifiable in this country in 1912, and some 200 to 300 cases were

reported annually until the war years, when mass concentrations of men were frequent, and housing accommodation for both civilian and soldier was strained to the utmost. In 1915–17 there was an annual incidence on the civil population of from 1,300 to 2,500. From that time the annual figures decreased to a minimum of 301 in 1923, but since that year their tendency, though irregular, has been upward. The total of notified cases in England and Wales in 1929 was 650, and in 1930 it was 666. Since the present year began, approximately 230 cases among civilians have been notified in England and Wales. In general they have shown the usual scattered distribution, and have occurred in as many as thirty-six counties. There has, however, been some concentration in the West Riding of Yorkshire, where 79 cases have occurred since the beginning of the year in twenty different sanitary districts.

The case mortality from cerebro-spinal fever varies with the epidemic and with the phases of an epidemic, and, naturally, with the extent to which the milder cases are diagnosed and reported. Of the cases at present occurring and reported, approximately half have proved fatal.

The wide diffusion of cases, with their occasional concentration here and there, is a characteristic of cerebro-spinal fever, not only in this country, but all over the world. This has been the case in practically all European countries and also in the United States, where the disease is, relatively speaking, more common. More severe and concentrated outbreaks from time to time occur in the East, probably associated with conditions parallel to those of the war years in England. The epidemic behaviour of this disease depends largely on the fact that in times of prevalence the responsible micro-organism (the meningococcus) is to be found in the nose and throat passages of a very large number of persons who are, and who remain, quite well. Contact with such persons is unavoidable, and little in the way of preventive measures can, in the circumstances, be taken, except those which are usually adopted or enjoyed to prevent the spread of ordinary catarrhs from person to person. Isolation of the individual case of cerebro-spinal fever is, on the whole, desirable, but, however effectively it is done, its influence on the spread of meningococcus infection can never be considerable. Infants, children, and young persons (especially when newly entrant to a large community—for example, recruits) are especially liable to the disease. One circumstance has been shown conclusively to favour local outbreaks—namely, overcrowding in barracks, schools, and other residential institutions, and in club premises for young people. It was found, particularly during the war years, that when the individual was given more room in which to live and sleep the incidence fell greatly. This point is of special importance in the prevention of outbreaks of the disease in these institutions in which no approach to overcrowding should be permitted. This applies particularly to dormitories, where insistence on sufficient space between the edges of adjacent beds (which should never be less than 3 feet clear) and the maintenance of thorough ventilation are of the greatest importance in preventing cerebro-spinal fever.

No vaccine or serum effective for the prevention of an attack of cerebro-spinal fever is known. There is, however, an important specific curative treatment by the administration of antimeningococcus serum, but its efficacy is by no means constant, and depends to a large extent on the particular type or types of meningococcus used in its preparation. Serum therapy thus sometimes yields brilliant results, but at other times they are disappointing, even when the serum has been recently produced and has been derived from the organisms responsible for the current type of disease. The continued identification of types, the appropriate modifications of serums, and the laboratory methods of determining the therapeutic potency of any given batch of serum, are among matters which are receiving close attention from many research workers and bacteriologists in this and other countries, in the hope of enabling serums to be prepared which promise greater success than those which are at present in use.

HEALTH SERVICES IN LANARK: PROPOSED CO-ORDINATION

A memorandum on the co-ordination of health services has been addressed to the Lanarkshire County Council by the Lanarkshire Medical Practitioners' Union and the local Division of the British Medical Association. The Lanarkshire Division numbers 258 members, but the memorandum claims to speak generally for all the practitioners in the county, which has a population—largely industrial, and Labour in its political sympathies—of well over half a million.

While recognizing the widening scope of the public health service, and abandoning the view that public health should be limited to preventive medicine, the framers of the memorandum remind the council that the first line in the fight against disease is occupied by the family practitioner, whose duty it is to recognize ill-health in the individual at its earliest and therefore most curable stage. The increasing encroachment upon the daily work of the general practitioner by the public health service, extending definitely to the therapeutic side of medicine, is noted, but it is pointed out that the development of the public health department of the county has now reached a point at which wider extension necessarily involves the appointment of general practitioners rather than specialists to its staff. This raises the question whether it is in the public interest that the public health service should continue to develop by the appointment of more whole-time officials until the ideal of a State medical service is attained, or whether the general practitioner should be brought into closer association. The excellent work done in the past by whole-time officials is fully acknowledged, but it is stated that the medical practitioners of the county consider that the time has arrived when the public interest demands that there should be closer co-operation between the two sections. They suggest that much clinical work, such as inspection and treatment of school children, maternity and child welfare, and domiciliary treatment of tuberculosis, could be efficiently performed by general practitioners on a part-time basis. "After all, these represent the day's darg* of every doctor in family practice." They also maintain that it is not in the interests of the public health service or of the people that this work should be undertaken by medical assistants whose experience and training is almost exclusively confined to the limited section of work in which they are engaged. When dependants are included in the health provisions of the national insurance scheme, the memorandum states that not less than two-thirds of the population of Lanarkshire will be affected, but that if the public is to obtain the fullest use of all the services available, it seems essential that the domiciliary medical treatment provided under the National Health Insurance Act should be brought into close relationship with the public health and hospital services of the county.

It is understood that the county council proposes at the moment to make no change in the terms of appointment of the medical officers who were appointed by the now defunct parish councils to undertake the medical treatment of the poor. Those practitioners whose opinion is expressed by the memorandum agree that existing appointments should not be disturbed, but they suggest that as and when vacancies occur the sick poor should have the same rights with regard to medical treatment as insured persons. There should be no segregation for the purpose of medical relief. A skeleton scheme is also submitted for the provision of facilities for diagnosis. It is pointed out that many patients could be efficiently treated at home, thus relieving hospital congestion, if certain diagnostic facilities, outside the means of the private doctor, were available, such, for example, as routine *x*-ray examination, electrocardiography, test meals, kidney efficiency determinations, and so forth.

* A good old Scottish word. "I have a lang day's darg afore me."—*Heart of Midlothian.*

The establishment of diagnostic centres affording these facilities would materially raise the standard of the medical service, and greatly assist in the medical treatment of the workers throughout the county. It is suggested that the staff should consist of general practitioners and of specialists in the various departments, all on a part-time basis and remunerated by a sessional fee. Advantage might be taken of such centres in connexion with the treatment of school children, and for the purpose of consultation by the regional medical staff, and they would form a most desirable liaison between the public health officers and the general practitioners. The memorandum also proposes that in the provision of general hospital beds, of which there is a definite shortage in the county, the general practitioners might be consulted with advantage, and that in any provision made by the county council the right of the general practitioner to treat his patient should be maintained, subject always to the regulations of the hospital authority. It is recognized that in all schemes of this nature the medical officer of health must be the supervising and controlling authority, but the importance of bringing in the general practitioner is stressed.

"It is not in the interests of the public health service that it should be formed of a series of officials who, while expert in one department or in one section of a department, may never have had that wide experience of the conditions under which the people live, without which knowledge and understanding it would appear that no measures can prove of permanent value."

The action of the Lanarkshire practitioners might well be followed by those in other localities. Materials for such memorandums may be found in reports adopted by the Representative Body.

Scotland

We publish at page 360 this week a note on the Royal College of Physicians of Edinburgh, which will commemorate its 250th anniversary next November. The celebration, which will extend for some three days, will include a religious service in St. Giles's Cathedral on Sunday, November 29th, a meeting for the conferment of the honorary Fellowship of the College on a number of distinguished physicians, a reception in the College Hall, and a banquet in the Freemasons' Hall.

The Morison Lectures

The Morison Lectures were delivered before the Royal College of Physicians of Edinburgh by Dr. D. K. Henderson, medical superintendent of the Royal Mental Hospital, Glasgow, on February 9th, 11th, and 13th. The lecturer chose as his subject "Social psychiatry," and said that mental hygiene was a public health question which should be placed on the same basis as physical hygiene, so that mental disease should be considered in terms of illness rather than in terms of wickedness and crime. It was not generally recognized that many patients were discharged from mental hospitals in a recovered or greatly improved condition; these amounted to over 50 per cent. of the annual admission rates. The majority of recoveries took place within the first twelve months after admission, and where residence in a mental hospital exceeded three years, a satisfactory recovery could rarely be expected. The voluntary group of patients made the best and quickest recoveries. With regard to mental defectives, improvement in educational and training methods, closer supervision, and the establishment of more training centres would have a beneficial effect. Many forms of disordered conduct were due to the individual's inability to adapt himself to the demands of everyday life, and a hopeful method of approach was to deal with those who had not yet developed any outstanding defect. The lecturer did not consider that much improvement would be gained by the modern eugenic proposals. Who was going to determine these matters? The only satisfactory method was to educate the public. The alcohol problem was not so serious as it had been, but while enlightenment and betterment were taking place in this country, he thought the opposite had occurred in the United States, as a result of premature legislation. Types of temperament, such as lymphatic, the melancholic, the nervous, etc., had been recognized from early times as broad groupings, but the correlation of temperament with definite types of mental disorder had been of comparatively recent date. They should endeavour to establish behaviour patterns which should be of help in picking out pre-psychotic types, so that treatment might be instituted at a time when success could be hoped for. The mentally disordered and the criminal were "misfits" of society, and success in dealing with them would be measured by the number which could be transformed into decent law-abiding citizens.

In the second lecture, Dr. Henderson spoke of the benefit that would result from a closer co-operation between the general hospitals and the mental hospitals, as well as between the doctor and the social worker. Psychiatry was the subject of medicine in which the general practitioner was worst educated. The psychiatrist, too, was often kept in the background, and treatment in a mental hospital was used as a threat. This lack of frankness, and hesitation in accepting an illness as psychically determined, eventually created distrust and lack of confidence. The lecturer thought that the present training of the medical student in psychiatry, which consisted merely of a few systematic lectures and the demonstration of groups of patients exhibiting gross symptoms, was insufficient, and that the danger signals and the early cases with which the medical man should be familiar, were either not observed or were neglected. The general hospitals at present failed to make adequate allowance for the psychological or functional element which might be an accompaniment of physical illness, and the student still thought in terms of symptoms rather than of personalities. There should be more treatment of patients, both for physical and for mental ailments, while they continued at their work or in their homes. He considered that the success of this method would depend on ability to dissipate the notions which were currently held regarding the awfulness of mental disorder, and on enlisting the cordial support both of the medical profession and of charitable institutions interested in social welfare.

Glasgow Victoria Infirmary

The annual meeting of the Victoria Infirmary of Glasgow was held on February 16th under the presidency of Lord Provost Kelly. Mr. William Gray, chairman of directors, referred to the new ward for paying patients, which will be ready for occupation in a month, with accommodation for thirty beds. He said that there was great need for institutional treatment for people of moderate means, whose finances were too severely taxed by the charges of private nursing homes. Many at present were being treated free in the wards of voluntary hospitals who would prefer to pay a fee if such an arrangement could be made. The directors desired to free such patients from financial worry by providing the best surgical treatment and nursing at a moderate expense. The hospital charge would cover the actual cost of nursing and maintenance, and the cost of surgical operations would be considerably lower than that at private nursing homes. He stated also that the new auxiliary hospital at Philipshaugh had been an unqualified success.

Patients had been removed from the city to attractive and healthy surroundings in the country, offering them a better opportunity for speedy recovery. With regard to the Victoria Infirmary there was a waiting list of 200 to 250 names. The report showed that 7,130 patients had been treated in the wards, including 255 cases due to motor accident. The income of the hospital amounted to £48,250 and the expenditure to £67,359. In appealing for increased subscriptions the directors emphasized the fact that the cost of maintenance now exceeds £67,000 per annum.

Royal Medical Society of Edinburgh

The annual dinner of the Royal Medical Society of Edinburgh was held on February 19th in the Hall of the Royal College of Physicians. Dr. W. I. C. Morris, senior president of the society, presided, and Sir Robert Philip was the principal guest. In proposing the toast of "The Royal Medical Society," Sir Robert said that this society had been founded nearly two hundred years ago, at the time when the medical faculty in the University was instituted, for there had been no medical faculty up to the year 1726. The University of Edinburgh had granted a degree in medicine, but neither taught nor examined for it at that time, relying upon the Colleges of Physicians and Surgeons for the instruction of students in Edinburgh, and on the College of Physicians for examining candidates for the M.D. degree. Referring to his own association with the society, he said that more than fifty years had passed since he became a member; he had no doubt that the training and experience gained by students in the society were of incalculable value. The freedom of discussion, the clash of mind against mind, and the fact that they had a body of men viewing subjects from different angles, all combined towards forming a common judgement of affairs. Dr. I. C. Munro proposed the toast of "The City of Edinburgh," and Lord Provost Whitson, in reply, referred to the work of the town council in reorganizing the hospitals which had come under its care from the parish council. If they succeeded in co-ordinating all the hospitals in the city, he said, there would be more facilities for clinical teaching, and the number of medical students would be increased. These results would be of great benefit to the city.

Teaching in Edinburgh Poor Law Hospitals

At a meeting of the board of managers of the Royal Infirmary of Edinburgh, held on February 16th, a letter was read from Lord Provost Whitson dealing with the provisions which are at present being made by the corporation of Edinburgh for accommodation in the hospitals taken over in May, 1930, from the parish council. It was stated that the corporation expected to make provision for 750 beds, which will be available for teaching purposes. In this connexion arrangements are being made with the University. The letter emphasized the fact that these proposals, at present under discussion, would not in any way affect the need for enlarging the Royal Infirmary, and that the town council would give every assistance in its power towards furthering the appeal for a sum of £500,000 for this purpose.

Dunfermline Hospital

The thirty-sixth annual report of the managers of the Dunfermline and West Fife Hospital states that the additions by legacy and gift to the capital of the hospital during the past year amounted to £38,965, including several large bequests. The annual income for the maintenance of the hospital from all sources totalled £11,258, an increase of £2,113 compared with the previous year. There was a credit balance in hand of £3,793. In view of the temporarily restricted accommodation owing to the reconstruction of the hospital, the number of admissions had fallen from 1,160 in 1929 to 942 in 1930. In addition to the new wards which have been opened, the heating, lighting, and drainage systems have been completely remodelled, and a large up-to-date out-patient department, separate from the remainder of the hospital, is in course of erection. It is expected that the reconstruction of the hospital will be completed by March of the present year.

England and Wales

Birmingham University and the Hospitals Centre Project

As already explained in these columns, Birmingham has a handsomely supported project for establishing a large hospital centre at Edgbaston, close to the University, with a general hospital of 740 beds, and a new medical school. At the annual meeting of the court of governors of the University on February 19th, the Pro-Chancellor, Sir Gilbert Barling, stated that there had been a good response to the appeal, which so far amounted to £600,000. The arrangement is that the University for the purpose of the new medical school will receive one-sixth of the sum realized, but Sir Gilbert Barling pointed out that £100,000 was not adequate for this purpose, and those concerned would like to see another £100,000 allocated. He announced also that during the year the University Grants Committee had had an additional £250,000 placed at its disposal by the Chancellor of the Exchequer, and of this sum Birmingham was to receive a sum of £10,000 a year for the next five years, making the annual grant from this source £76,000. The committee had now given an additional £2,000 for the library and £5,000 to be spent on athletics. The Principal, Sir Charles G. Robertson, in a further reference to this supplementary allowance from the University Grants Committee, said that there was an idea that it was to be devoted largely to increasing the salaries of the professorial and non-professorial staffs, but in fact neither the universities, who had sent a deputation to the Chancellor of the Exchequer on the subject, the Chancellor himself, nor the committee, were pledged that any proportion of the money should necessarily be devoted to the augmentation of salaries, although he himself hoped that some review of salaries would be made. He also discussed the report of the committee on research at Birmingham University, saying how much he was impressed by the extent as well as by the quality and variety of the work done. He wished to emphasize a passage which he wrote in the council's report as to the over-development of the social side of undergraduate life. While in no way wishing to restrict their pleasures, he had reminded the students that their main purpose at the University was to work, and that engrossment on the social side meant a lessening of the number of working hours available, and possibly a diminished fitness for work during those hours. In this connexion the *Birmingham Daily Post* points out that a non-residential university in a great town is a very difficult problem, and Birmingham has tackled it, so far, by giving undergraduates the maximum of liberty. It takes the Principal's remarks as meaning that some restraint will have to be imposed, and says that that restraint will be at once more tolerable and more effective if it is achieved by co-operation between the students and the authorities.

Hunterian Society Annual Dinner

Professor A. W. Sheen, the first Welshman to hold office as president of the Hunterian Society of London, was in the chair at the annual dinner held in the May Fair Hotel on February 19th. The occasion was interesting also because it was the first time that a member outside the London area had been appointed to the chief office. Among the distinguished guests present were the Lord Mayor and Lady Mayoress and the Sheriffs of London, the Presidents of the Royal College of Physicians and the Royal College of Surgeons, the Masters of the Society of Apothecaries and of the Cutlers' Society, the Presidents of the Royal Society of Medicine, the Medical Society of London, the Harveian Society, the Chelsea Clinical Society, and the West London Medico-Chirurgical Society, and Mr. G. Buckston Browne. After the usual loyal and patriotic toasts, Sir Basil Blackett proposed the "Hunterian Society," saying that John Hunter was a man of extraordinary characteristics, a likeable man to those who liked him. He was always experimenting; he was never satisfied with things as they were. He showed the venturesome spirit so much required by the younger generation to-day. Replying, the President made reference to Mrs. Hunter; she was undoubtedly a woman of outstanding character who had probably had much to do with the success of her husband. It would be fitting, he thought, if a Hunterian Lecture were devoted to Mrs. Hunter. The toast, "To the Memory of John Hunter," was drunk by the guests standing and in silence. Replying to the health of the Lord Mayor and Corporation, Sir William Phené Neal commented on the work of the modern hospitals, and said that if he were seriously ill he would rather go to a hospital than be treated in his own home. Sir Arthur Keith proposed the toast of "The Guests," which was replied to, first, by Lord Moynihan, and secondly, by Lieut.-Colonel C. T. Samman. Lord Moynihan eloquently described the attributes of the man they were met to honour that night, and said that Hunter had been the great example in the world of surgery. Although he was of the opinion that surgical accomplishment had reached its limit, he was proud to think that, thanks to the munificence of Mr. Buckston Brown, surgical biological research could be carried on indefinitely, and therefore the future of surgery was assured.

Central Midwives Board

At the February meeting of the Central Midwives Board for England and Wales a letter was read from the Queen's Institute of District Nursing, stating that it had re-elected Mrs. Elena Richmond as its representative on the Board for the year commencing April 1st next. A communication was received from the Incorporated Midwives Institute requesting that the names of midwife-teachers holding the diploma of the Institute might be placed on any list of such teachers issued by the Board or on any roll of teachers instituted by Act of Parliament. It was agreed to reply that those midwives who had passed the teachers' examination conducted by the Institute would be placed in the same position as those who passed the Board's examination for midwife-teacher. A letter was read from the medical officer of health for Norwich, drawing attention to that part of Rule E.8 which requires a midwife to wash the patient's external parts with soap and water, and then swab them with an efficient antiseptic solution on certain occasions, and asking whether the wording of the rule requires the midwife to perform such duties personally. It was decided to send the following reply:

"That the Board is of opinion that the duties imposed by Rule E.8 must be performed by the midwife or by a certified midwife acting as her substitute. It would be regarded a breach of the Act if a midwife employed an uncertified woman. It should be noted that Rule E.8 applies to surgical washings. The position of a midwife under Rule E.12 is somewhat different, as under that rule a midwife is only required to supervise personally and be responsible for the cleanliness, etc., of the patient. This supervision can be exercised and the responsibility assumed, even if the midwife is not present when ordinary washings of the patient take place. It will readily be understood that a midwife cannot be expected to be present on every occasion when an ordinary washing is necessary. The delegation of the midwife's responsibilities under Rule E.12 must not be made to an uncertified woman."

The Standing Committee reported that owing to his election as a member of the Board, Mr. Comyns Berkeley had resigned his appointment as one of the Board's examiners. Mr. Comyns Berkeley had held the appointment of examiner at the London centre during the whole of the time the Board had conducted examinations, and the Board had profited much, not only by the way in which he has carried out his duties as examiner, but also by the valuable advice on examination matters which he had from time to time given to it. It was agreed that the best thanks of the Board be given to Mr. Comyns Berkeley for his valuable services. The Board recorded its sympathy with the family of the late Dr. J. E. Gemmell, and its appreciation of the services rendered by him as an examiner at the Manchester-Liverpool centre.

A Hospital Contributory Scheme

We have received an account of the year's working of the North Walsham (Norfolk) Hospital Saturday and Sunday Fund, which covers a small country town and adjoining rural districts. The membership of the fund is 1,800, and, on the basis of contributions of twopence a week, an annual income of over £700 is received, about half of which goes to the Norwich Fund, where it assists the central hospital, the Norfolk and Norwich, at which many of the contributors receive benefit, and the other half goes to a local account, largely in support of the excellent cottage hospital at North Walsham. Thanks, evidently, to much voluntary work, the cost of the administration of the fund is negligible. At the annual meeting, held on January 29th, Dr. C. H. W. Page, who has been president of the fund since its inception ten years ago, mentioned that £50 had again been voted towards the staff fund of the local hospital. This fund was started two years ago with a nucleus contributed from the same source. Its purpose, said Dr. Page, was to assist in meeting the out-of-pocket expenses of practitioners who gave their services in an honorary capacity to the hospital, and although this was not a payment for such services, but only a recognition of them, it had been much appreciated by the doctors concerned. The contributory scheme has also assisted the endowment fund of the local hospital, the local nursing association, and the new nurses' home at the Norfolk and Norwich Hospital, while a modest donation has been sent to St. Bartholomew's, on the very sound principle that even the more rural parts of the provinces have a definite interest in the great teaching hospitals. At the North Walsham Cottage Hospital the medical men of the locality are invited to act as honorary medical officers; each officer has charge of his own patients, but each takes duty for one week in rotation, with charge of all patients admitted during that week, transferring such as are not his own to their own medical attendants as soon as possible; while any practitioner in the district who has one of his patients in hospital may, if the patient desires and the medical staff agree, attend that patient in the institution. The general committee is empowered to contribute to the staff fund from the moneys received under contributory funds up to a maximum not exceeding 5 per cent. of the ordinary hospital income.

Ireland

Northern Ireland Vital Statistics

According to the Registrar-General's quarterly return for the three months ending December 31st, 1930, which has just been published, the numbers of births, deaths, and marriages registered show an increase on the numbers registered in the corresponding quarter of the previous year. The equivalent annual birth rate for the quarter under review was 19.6 per 1,000 of the population, as compared with rates of 15.4, 18.8, and 18.6 for England and Wales, Scotland, and the Irish Free State respectively. The equivalent annual death rate was 13.3 per 1,000, the corresponding rates for England and Wales, Scotland, and the Irish Free State being 11.5, 13.0, and 13.4. Deaths from the principal epidemic diseases and tuberculosis show, on the whole, a considerable decrease when compared with the average numbers of deaths from these causes in the fourth quarters of the five preceding years. The deaths from cancer, however, continue to increase; the number recorded for the quarter under review showing an increase of 12 per cent. on the average numbers registered in the corresponding quarters of the five preceding years. A summary of the quarterly returns for the year shows that the deaths registered numbered 17,171, giving a rate of 13.8 per 1,000, which is the lowest death rate yet recorded for Northern Ireland. The births numbered 25,953, the rate being 20.9 per 1,000, and the marriages 7,529, a rate of 6.05 per 1,000. The infant mortality during the year was 66.5 per 1,000 births registered, an appreciable decrease on the figures for 1929. The quarterly return is published by H.M. Stationery Office, 15, Donegall Square West, Belfast (price 1s.).

County Down Mental Hospital

In a report on a recent inspection of the County Down Mental Hospital, Dr. Patrick states that since the last, in December, 1929, when 774 patients were on the register —401 males and 373 females—130 have been admitted, 54 have been discharged, and 53 have died. As in previous years, cardio-vascular disease was a factor in nearly 50 per cent. of the deaths. In 14 cases tuberculosis was present. Twelve post-mortem examinations were made. Twenty-one cases of zymotic disease occurred, two of the staff being affected. Of these, 17 were of the intestinal group, and resulted in two deaths among the patients; the source of infection was not traced. Patients with epileptic and suicidal tendencies under special observation numbered 182. The introduction of occupational therapy, which consists at present of the weaving of tweed and linen, basket-making, wire work, rug-making, leather work, and raffia, is stated to have been of the greatest benefit, and its success calls for the provision of more extensive workshop accommodation, so that a larger number may be employed. The general tone and condition of the institution is reported to be excellent in every way.

Enniscorthy Mental Hospital

In his report on the Enniscorthy, County Wexford, Mental Hospital, Dr. D. L. Kelly, inspector of mental hospitals, states that at the time of his last visit there were 529 patients on the register. Since the previous inspection 76 patients had been admitted, 27 had been discharged, and 48 had died. The institution is estimated to accommodate 525. In the hospital 30 patients were confined to bed—13 men and 17 women. The majority of these were suffering from senility, only 3 being acutely ill. The report emphasizes the need for two verandas to deal with the large number of tuberculous cases. It is suggested that amusements, such as handball and football, should be organized, and that a weekly dance should be held during the winter. In regard to the staff, ten of the male attendants hold a certificate in mental nursing, and seven attendants and five nurses have taken the first part of the examination. Instruction has been given to ten others who are preparing for the certificate. Dr. Kelly points out that the committee should insist that all members not in possession of the nursing diploma should attend these lectures and demonstrations. He also recommends that the practice of allowing patients to stay with friends on trial should be extended.

Correspondence

X-RAY THERAPY IN MALIGNANT DISEASE OF THE LUNG

SIR,—Dr. Ff. Roberts, in your issue of February 14th, criticizes Mr. Tudor Edwards's sceptical attitude towards the *x*-ray treatment of malignant lung tumours, and goes on to assert that he has had cases in which there has been "undoubted material benefit as regards alleviation of symptoms and prolongation of life." This is a vague phrase, and Dr. Roberts would be doing a valuable service if he would amplify his statement and give figures and actual results.

In the *Lancet* of September 17th, 1927, with Dr. Carlyle T. Potter, I published the results of a follow-up of 120 cases of primary malignant intrathoracic tumour. Of 59 such cases treated by *x*-ray therapy, one recovered, and that was a mediastinal lymphosarcoma with secondaries in the neck. Many have expressed surprise at such a small percentage of cures, but no one has ever shown me better. My article was largely written to stimulate criticism and correspondence, and I had hoped for contradiction, but not a voice was raised. I sometimes wonder if we are really justified in recommending *x*-ray treatment in these cases, especially in *lung* tumours, which, if primary, are always carcinoma, for it seems, alas! so futile.

If the results are not so bad, why does no one publish final results? I have had a very large experience of this type of tumour, and I grow more disheartened. *X* rays, radium, surgery, drugs; early cases, late cases—always the same result. Nevertheless, the disappointment must spur us on to further effort and not paralyse us. But it will not help if we deceive ourselves and believe that our achievements are better than they are.—I am, etc.,

F. G. CHANDLER, M.D., F.R.C.P.

London, N.W.1, Feb. 17th.

THALLIUM AND ITS RISKS

SIR,—We were surprised to learn from an article on thallium and its risks, appearing in the *Journal* of February 21st, that the English Board of Education has interdicted the use of this drug in the treatment of ringworm in school children. We presume that this applies to the internal administration of thallium in such cases.

It has been known for the past thirty years that thallium, like other heavy metals, is a poisonous substance. Since 1918, however, severe toxic symptoms have occurred only as a result of very gross errors in dosage, and when compared with other drugs such untoward results have been rare. It is true that a proportion of children who have received an epilating dose of thallium subsequently develop transient mild muscular pains. There is no evidence that any further deleterious effects occur, and the children afterwards gain weight and develop

normally. In certain cases which have been reported as instances of severe thallium poisoning following the administration of an epilating dose the symptoms may well have been due to some intercurrent condition. In one case in our series symptoms suggestive of severe thallium poisoning (including meningismus and abdominal pains) were in reality due to the presence of *Ascaris lumbricoides* in the duodenum.

Up to the present time about 3,000 cases of ringworm of the scalp treated with thallium acetate have been reported, and only four or five instances of intoxication have been noted. In three instances the result was fatal, but in these ten times the therapeutic dose had been given. When the advantages of thallium over *x* rays are considered, especially in the treatment of a large number of cases occurring during a short space of time, such as happens in school epidemics, it seems unwarrantable to condemn the use of this drug on account of one or two dispensing errors.

Nothing whatever is known of the mechanism by which thallium produces temporary alopecia. An intermediate action on the central or autonomic nervous systems, or on the endocrine glands, has been suggested by several authors. Such views are only based on the finding, post mortem, of petechial haemorrhages in the meninges and cerebral cortex, and of degenerative changes in one or more of the endocrine glands, in animals which have received a fatal dose of thallium. The supporters of these theories have brought forward no direct biological evidence to substantiate them. Furthermore, the normal influence of these systems on hair growth is not yet understood. This subject is fully discussed in the *British Journal of Dermatology and Syphilology* (1930, xlii, p. 59).

The therapeutic use of thallium has not been interdicted in cases of tinea capitis occurring in schools under the control of the Education Department for Scotland. We have administered an epilating dose of thallium to over 200 children, attending Edinburgh schools, or inmates of Craiglockhart Hospital, with results which were eminently satisfactory from the therapeutic standpoint. We have met with no instances in which severe toxic symptoms were caused by this drug.

We are in entire agreement with the suggestion that the employment of thallium in commercial depilatory creams should be strictly forbidden.—We are, etc.,

Skin Department, Royal Infirmary, Edinburgh, Feb. 23rd. FREDERICK GARDINER. G. H. PERCIVAL.

MORTALITY IN ACUTE APPENDICULAR DISEASE

SIR,—I have read with interest the article in the *Journal* of February 14th by Professor D. P. D. Wilkie on this subject, and wish to congratulate the author on its exposition.

Those who spend their time in the presence of the acute abdomen will whole-heartedly endorse the pronouncements of Professor Wilkie regarding the classification of the diseased appendix. Not all, however, will be content to follow his lead into the land of explanations as to the continued high mortality. It is Utopian to think that earlier diagnosis of the obstructive case by the family physician will permit the surgeon to remedy matters. Not till everyone, from the simplest citizen, acquires the tactile sense of the expert clinician can this be possible. Only recently I removed a ruptured, obstructed, and gangrenous appendix four hours after the first symptom. This is not uncommon. Many, I fancy, dealing with the peritonitic abdomen must feel, as I do, that it is we surgeons who must accept a percentage of the responsibility and find out where we fail.

Professor Wilkie admits that the ruptured appendix and the consequent peritonitis remain the cause of the high mortality. Since the disease is often more rapid in its progress than can be remedied by improved transport, it is, then, our clear duty to unearth our weakness in the treatment of the fully established case. Reviewing my own cases over the past five years, I doubt if I could place one death at the door which Professor Wilkie marks with a cross—namely, the wound. It may aggravate matters, but the mysterious physiological catastrophe that leads to the continued unsatisfactory mortality is within the abdomen. I agree that the peritoneum has a wonderful power to deal with infection, and that the mere infection is seldom the cause of death. We must look beyond either of these factors. It is the sequel to the peritonitis, a sympathetic crisis, that has baffled our efforts. If we realize this, the remedy for this aberration from normal physiology may not be far to seek, and the mortality from acute appendicitis be effectively reduced.—I am, etc.,

Gilbert Bain Hospital, Lerwick, Feb. 18th. JOHN J. ROBB.

SIR,—Like Mr. Rayner, after reading Professor Wilkie's paper on the mortality of acute appendicitis in the *Journal* of February 14th, I felt that there was a call for possible criticism. It may be that the experiences of hospital surgeons vary very widely, due, perhaps, to the local and district conditions of the community which a particular surgeon serves, but it has certainly been my experience that the mortality rate of acute appendicitis is less than it was twenty years ago. I would go further than this, and seriously suggest that it is less than it was ten years ago.

I have looked very carefully into my hospital figures, and, over a period of ten years, the mortality rate of all forms of the disease was 2.6 per cent. Over 400 cases were operated on in the acute stage, and the mortality rate was 3.5 per cent. Over a three-year period the mortality rate in females was 7.3 per cent. Acute appendicitis cases formed 52.6 per cent. of the total emergencies. In acute gangrenous appendicitis with perforation the mortality rate over the ten-year period is certainly higher, being 16.8 per cent.

It would be interesting, and perhaps instructive, if Professor Wilkie could persuade (and doubtless he could) hospital surgeons all over the country to make up their statistics, and, were this done, I believe he would be satisfied that acute obstructive appendicitis is being more and more recognized by the general practitioner, and that, as a result, the operation is being performed at an earlier stage.

Many surgeons, like myself, have benefited from Professor Wilkie's teachings on this disease, and any criticism that may be offered is certainly not intended to be destructive.—I am, etc.,

R. BERTRAM BLAIR,
Honorary Surgeon, Hull Royal Infirmary.
February 23rd.

THE ENIGMA OF THE CHILBLAIN

SIR,—I have read with interest and pleasure Dr. Rupert Hallam's article on chilblains in your issue of February 7th. His happy choice of the term "enigma" appears to be endorsed by the diversity of views of your correspondents.

As regards Dr. Izod Bennett's letter, unless I have read into it a meaning quite unintended by the writer (in which case I apologize), it suggests that there is really no enigma at all! With that view I do not agree. Nobody denies the importance of cold as a factor. Dr. Hallam in his first paragraph says: "It is known that cold is the exciting cause." But when Dr. Bennett says,

"The all-important factor in the production of chilblains is the shibboleth . . . of cold bedrooms which has come to us from our Victorian forebears," I venture to think that he goes, not only beyond the facts, but that he is also a little unjust. At the present day so many of the country's ills are heaped upon Victorian shoulders that a few chilblains more or less will not, perhaps, make much difference. Still, it is just as well to be fair, and, seeing that chilblains have been so called for a very long time, and that nearly a century before the Victorian era Johnson derived the word chilblain from "chill, cold, and blain," and defined it as "sores made by frost," it seems hardly necessary to lay the blame on Victorian bedrooms.

Even if chilblains should be prevented in this country "by discipline and common sense," as Dr. Bennett's letter seems to suggest, the problem to which Dr. Hallam has called attention would not be solved thereby; it would merely become one of academic interest instead of, as now, of practical importance. The problem itself seems clear enough. To quote Dr. Hallam's own words: "How one individual escapes and another suffers has never been determined." May I put it in a more concrete form, using Dr. Bennett's graphic, if somewhat dramatic, terminology? Suppose that Mr. and Mrs. X (true to their Victorian upbringing) sleep in the same "arctic bed," and place their "numbed" feet on the same "burning hot-water bottle," and, next morning, they "thaw their frozen hands and feet" before the same "glowing fire," why is it that Mrs. X suffers from chilblains, whilst Mr. X does not, or vice versa? It seems to me that until this question is answered "the enigma of the chilblain" still remains.

Personally, I think that the problem is well worth scientific investigation, and that its solution would have effects reaching considerably beyond the confines of dermatology.—I am, etc.,

Sheffield, Feb. 23rd. ARTHUR J. HALL.

GONOCOCCAL RHINITIS

SIR,—In the *Journal* of February 14th you publish an article under the above heading. The authors invite criticism and discussion. I would suggest that (if the facts are as given) such a diagnosis is quite unjustified.

To suggest that because Gram-negative intracellular diplococci have been found in the nose therefore they are gonococci, even if the father's ancient history recalled an attack of gonorrhoea years ago, is really too much! Why not meningococci or a host of other breeds? Why are the authors so sure that *Micrococcus catarrhalis* never becomes intracellular? Unless these cocci were cultured and submitted to fermentation tests, I contend that the authors were not justified in labelling them gonococci. This leap to a wrong conclusion because Gram-negative cocci have been found in a cell is becoming very common, and it leads to endless trouble. In obvious cases a diagnosis, together with clinical signs, may be justified by finding Gram-negative intracellular cocci, but in doubtful cases I contend that such a diagnosis as gonococcal rhinitis should never be made without confirmation.—I am, etc.,

E. W. ASSINDER.

General Hospital, Birmingham, Feb. 18th.

SIR,—I was much interested in the case of gonococcal rhinitis in an infant reported by Drs. Kirkland and Storer (*Journal*, February 14th, p. 263), but I cannot help feeling that further investigation should have been made before the diagnosis was arrived at.

It appears to be somewhat dangerous, in view of the unusual situation of the gonococcal infection, to tie oneself down to such a diagnosis on the strength of the morphological appearances of the organisms in the smears. It should have been possible to confirm the cause of the condition by isolating an organism from the nasal mucous membrane conforming to the cultural reactions of the gonococcus. Furthermore, no conclusive evidence that the father of the child was suffering from a gonococcal prostatitis was adduced. The presence of pus in a prostatic bead is not of necessity due to the gonococcus, but may be caused by such organisms as staphylococci or coliform bacilli, even although there be a history of antecedent gonorrhoea. A negative Neisserian infection reaction seems to point to the fact that the prostatic condition was not due to the gonococcus. Finally, no bacteriological or serological evidence of gonorrhoea in the mother was demonstrated.

In conclusion might I add that the complement fixation test for gonorrhoea, as performed in this laboratory, is almost invariably positive in cases of gonococcal prostatitis and cervicitis.—I am, etc.,

I. N. ORPWOOD PRICE,
Mile End, E.1, Feb. 16th. Pathologist, Whitechapel Clinic.

SIR,—With reference to the case reported by Drs. Kirkland and Storer, I should like to describe a similar one seen recently.

A baby, 15 days old, was sent to the Elizabeth Garrett Anderson Hospital from a children's hospital with urgent request for admission as a case of "frontal sinusitis."

There was a history of swelling of the nose, which had lasted about two days. The midwife who brought the child said that she had attended the mother at her confinement at home, that the labour was quite normal, and that there was no sign of gonorrhoea. The nose was swollen about three times the normal size, especially at the upper part. There was no discharge from the nose or eyes. A swab was taken from the nose, and gonococci were found. Discharge began from the nose the following day, and both mother and child were transferred to a special hospital.

—I am, etc.,

London, W.1, Feb. 19th. ELEANOR LOWRY.

FAMILIAL INCIDENCE OF CANCER

SIR,—I have noticed in the *Journal* some correspondence on the familial incidence of cancer, and it occurs to me that the following bare facts may be of interest in this connexion.

From 1886 to 1902 I was in practice in Barnstaple, and was also medical officer of health to the urban district council. I used to receive from the registrar of births and deaths a weekly list of the deaths occurring within the town. From this register the following facts are derived. During a period extending over about five to seven years, three brothers died successively of malignant disease of the rectum. I use the word "malignant" as no necropsy was performed in either case. The diagnosis was made by my then partner, the late Joseph Harper, a man of high repute in the town. I knew the patients personally, and had attended them at various intervals. They were all builders, though one was the licensee of a public-house as well. I also attended a grandson of one of the three brothers; this boy died at about 19 years of age from sarcoma of the lung. I regret that I know nothing of the parents of the three brothers, or of the cause of death in the father of the lad who died of sarcoma of the lung, although I knew him well.

There are one or two interesting questions raised by these facts. Naturally the first is: Was there any hereditary influence at work? They are the strongest evidence I have met with as to the influence of heredity.

The three brothers lived in different parts of the town, so that contagion may, I think, be excluded. Early in my practice I read Cohnheim's *Pathology*, and a great impression was made on my mind by his theory of the nature of cancer. On his hypothesis it would be quite natural to assume that a colony of embryonic cells, having the same origin from one or other of the parents, had in each case developed on similar lines in each of the several subjects. It is very remarkable that they all showed an affinity for the same site in the body, and that they should have developed in each case at relatively the same period of life—about 65 years of age, or a little later. I intended to publish more detailed accounts of this series of cases, but left Barnstaple in 1902. I ought to say that I have written this note entirely from memory.—I am, etc.,

Bexhill-on-Sea, Feb. 10th. MARK JACKSON, M.D.

TREATMENT OF ETHMOIDITIS

SIR,—In reply to Mr. Peters's letter in the *Journal* of February 14th (p. 286), I wish to point out that my criticism of his article was directed not so much to the routine removal of the middle turbinal as to the actual method of removal which he mentions—namely, with a Luc's forceps. This is just an operation in which that useful instrument cannot be used with safety, as it can but result in avulsion of the turbinal. This means that the outer wall of the "danger area" (or, in other words, the inner surface of the middle turbinal) is torn across at some indeterminate level, hence the danger. If Mr. Peters will try my transantral method of removing degenerated ethmoidal tissue he will be surprised at the facility and clarity with which this can be accomplished without interfering with the middle turbinal.

With regard to his remarks about radiography and the frontal sinus, I would remind Mr. Peters that my previous letter (like his article) related to the *treatment* of ethmoiditis. I quite agree with him that radiography is a necessary step in the *diagnosis* of nasal sinus disease.—I am, etc.,

Cork, Feb. 16th. J. B. HORGAN.

ANTIDIABETIC DIETS

SIR,—All post-mortem reports on the pancreatic glands of those who have died of beri-beri or pellagra record an increased development of the islets of Langerhans, and all clinical reports record an exaggerated ante-mortem sugar tolerance. These two diseases being now practically proved to be due to diet deficiency—to vitamin deficiency—one naturally presumes that by some diet deficiency, analogous to that which produces these diseases of excessive sugar tolerance, we should be able to get rid of that one disease which is accepted as being due to loss of the glandular tissue of the islets of Langerhans. In this connexion paragraph 527 in your *Epitome* of December 13th, 1930, recording seventeen cases of diabetes treated by a deficiency diet, of which sixteen were apparently cured, is of serious interest. The specialists who by laboratory work have built up our knowledge of vitamins seem to have little opportunity for human experiments. But among your thousands of readers there are likely to be some who would have both the desire and the opportunity to test deficiency diets on diabetic patients were they provided with the necessary information as to forms of deficiency diets most likely to restore the islets. Our Association might thus be of valuable world service.—I am, etc.,

J. BARCROFT ANDERSON.

East London, Africa, Jan. 21st.

LONDON CLINIC AND NURSING HOME

SIR,—I have read with great interest the letter of the executive committee to the medical advisory board of the London Clinic and Nursing Home, appearing in the *Journal* of February 14th (p. 287). I agree entirely with the ideals of the promoters, and think there is a real need for an institution of this kind. May I, however, criticize the claim made in the last paragraph of the letter that "this is the first real effort in this country to extend the advantages of an organized specialist service to those who are excluded from the services of charity"? Sixteen and a half years ago St. Chad's Hospital was opened in Birmingham, and since then has dealt with an average of about 1,000 patients a year.

The desirability of a self-supporting non-charitable institution where patients of moderate means can obtain the advantages of the accessory departments and team work of the large voluntary hospitals, and yet can retain the privacy and other amenities of a nursing home, was realized by a group of consultants. Sufficient public interest was aroused to enable a public company to be formed to finance and carry through the building and equipment of a "pay hospital" of 100-bed capacity. An account of St. Chad's Hospital and its work has already been published (*Journal*, 1920, i, 263). The institution, and the ideals of which it is the embodiment, are widely known in medical and other circles.

All the essential features outlined in the letter of the executive board of the London Clinic and Nursing Home, with the exception of expensive suites for wealthy patients and the medical clinic containing consulting rooms in close relationship to it, are provided by St. Chad's Hospital. There is a resident medical officer, a maternity department, with its delivery room, nursery, suite of private rooms for the patients, and special expert nursing service, an *x*-ray department, pathological laboratories, dispensary, two operating theatres, etc. The hospital has been recognized by the General Nursing Council as a training school for nurses, and its constitution is approved by the Royal College of Physicians. The shareholders of the company receive a restricted dividend of 6 per cent., and medical men connected with the hospital are free to invest in it if they wish, the limited dividend they can receive solving the ethical problems involved. Any member of the staff of a Birmingham voluntary hospital which confers consulting status is eligible for election to the staff of St. Chad's, which at present consists of thirty-four specialists in the various departments of medical work.

St. Chad's Hospital, in spite of the low charges made for nursing-home accommodation, etc., has met all its financial obligations with a moderate surplus, out of which improvements have been made and additional equipment provided. Its record over a period of many difficult years, including those of the great war, inspires confidence in the future of the London Clinic and Nursing Home.—I am, etc.,

Birmingham, Feb. 17th. WILLIAM BILLINGTON.

SIR,—We appreciate the opportunity which Mr. Pearce Gould has given us of laying stress upon several important points in the organization of the London Clinic and Nursing Home. To make the position entirely clear we will answer the questions in order.

1. General practitioners will be able to admit patients to the London Clinic under their own care or under the care of a consultant, whether he be connected with the group or not. They will, in fact, have facilities in every way similar to those enjoyed at any of the present nursing homes, but the reasonable stipulation is made that operations shall only be performed in the theatres by surgeons on the staff of a recognized hospital.

2. With regard to prices of the rooms, a large proportion will be provided at fees ranging from eight to fourteen guineas a week. This will include all diets, whether special or otherwise, all ordinary nursing service, and all drugs contained in the Clinic Pharmacopoeia.

3. Fully equipped laboratories and *x*-ray departments will be provided under the control of specialists, where investigations in pathology, bacteriology, chemical pathology, or changes in metabolism can be carried out at current charges without the patient leaving the nursing home. The services of the laboratories will be at the command of any patient, whether under the care of a member of the group or of any other doctor.

4. Any consultant will be able to admit cases as in other nursing homes, and will be able to enjoy the same facilities.

5. Those consultants connected with the group—that is, having consulting rooms—will have the benefit of being situated adjacent to the home; of being on the advisory board so that they can guide the development of the clinic along modern medical lines; of having the first claim upon vacant rooms; of having the benefit of constantly meeting colleagues engaged in other branches of their profession; and it is hoped, in the near future, of evolving a scheme whereby poorer patients may be enabled, on the payment of small inclusive fees, to obtain a complete examination by different members of the group at the request of the patients' own general practitioner. It is only such patients, who may for convenience be called "group patients," who would be required to see different consultants connected with the group. All other patients or their private medical advisers would be free, even if admitted by one member of the group, to see any other consultant, whether connected with the group or not. In fact, it is proposed to conform in every way with the established methods of medical practice, but to enable the patients and their own medical advisers to obtain those facilities which to-day are found in the larger hospitals.

—We are, etc., THE EXECUTIVE COMMITTEE OF THE MEDICAL GROUP, LONDON CLINIC AND NURSING HOME.

London, W.1, Feb. 24th.

MEDICAL RECIPROCITY WITH FRANCE

SIR,—Pray what is the matter with Dr. Gerald Stanley that he should write in such a morbid strain of medical practice in France? I have had something like thirty years' experience thereof, and am by no means despondent. What does tend to depress me is the fact that, judging from appearances, we British practitioners abroad do not seem likely to have successors of our own nationality when we depart. And that is a pity, because practice among Anglo-American folk in the Continental health resorts is very agreeable. One meets so many distinguished and otherwise delightful people, and practice is by no means exacting. The summer in Algiers, for instance, is one long holiday, and an enjoyable one at that, for the heat is far less trying than that of Paris or London.

I have on more than one occasion endeavoured in the British medical press to call the attention of British parents to the splendid field for medical practice afforded by foreign health resorts for their offspring. True it is that aspirants for Continental medical practice will have to take a State degree entitling them to follow their bent, but the only real difficulty is the *baccalauréat*, but even that need not scare them away. All that is necessary is that they should spend a year or two in a French *lycée* to learn the language and to get *pistonné* through the *bachot*. Moreover, this matriculation examination is, I believe, accepted by many of the English collegiate authorities in lieu of their own, should the candidate be desirous of taking an English qualification at the same time. When I was a student I put in an appearance at both Paris and London lectures during alternate fortnights. The purely professional examinations are, of course, virtually the same on both sides of the Channel. That was the time of my life—from Westminster to the Boulevard St. Michel, and vice versa.

I doubt whether there will ever be reciprocity—the French are far too protectionist for that. Nor is there any particular necessity therefor; it is so easy to elude the protection by complying with the regulations.—I am, etc.,

Algiers, Feb. 3rd. ALFRED S. GUBB, M.D.Paris.

Obituary

SIR ROBERT WILLIAM BURNET, K.C.V.O.

M.D., F.R.C.P.

Formerly Physician to the Royal Household

The death took place on February 20th, in his eightieth year, of Sir Robert Burnet, who was physician to the Royal Household from 1910 to 1919. He had been living for some years at Budleigh Salterton, in Devonshire, after retirement from practice.

Robert William Burnet was born at Chryston, a village seven miles from Glasgow, where his father was minister of the Free Church of Scotland. Like Sir Henry Campbell-Bannerman, whose close friend and medical adviser he afterwards became, Burnet was a scholar at Glasgow High School. Later, his family having moved to Aberdeenshire, he entered the University of Aberdeen, where he graduated M.B., C.M., with honours, in 1876, and took the M.D. in 1878. For a short time he held an appointment at the London Hospital, where he attracted the attention of Sir Andrew Clark, who was one of its then physicians, and for five years he served as Clark's private secretary and assistant. Probably it was Sir Andrew Clark's example which led Burnet to cultivate the habit of writing most elaborate directions as to regimen for his patients, such as the hours at which food should be taken, the quantities that should be given, and the dishes to be permitted or avoided. Like his master, he was most meticulous in this respect.

In 1879 Burnet followed the late Poet Laureate, Dr. Robert Bridges, as physician at the Great Northern Hospital, then at King's Cross, now the Royal Northern in Holloway Road. He began his work as physician to the out-patient department, and the institution retained his interest during the whole of his career. He served it not only as a physician on its staff, but as an adviser and administrator in connexion with its various schemes for reconstruction and enlargement. On his resignation after twenty years on the full staff, all his colleagues bore the most cordial testimony to his services, and he was elected consulting physician, a post which he retained until the end of his life.

When Lord Lorne, afterwards Marquess of Argyll, with Princess Louise, went to Canada in 1882 to take up the duties of Governor-General, he was accompanied by Sir Andrew Clark. Dr. Burnet, then Clark's assistant, afterwards went as medical attendant to the viceregal household on the journey across the continent to British Columbia. Lord Lorne prided himself on the large Scottish element in his entourage, and took a special interest in this young Scottish doctor. Desiring that the Scottish people should learn something about the then unknown country of the Canadian Pacific, its genial climate, and its opportunities for settlers, Lord Lorne asked Dr. Burnet to write his impressions, and this he did from Government House in the form of letters to the *Scotsman*.

Burnet's connexion with the Royal Household began in 1894, when he became physician in ordinary to the Duke of York (the present King); during the next reign

he continued as honorary physician to the Prince of Wales, and on King George's accession he was appointed physician to H.M. Household, a position which he retained for nine years. He was elected F.R.C.P. in 1894.

One of his distinguished patients, as already stated, was Sir Henry Campbell-Bannerman, and during the last few years of that statesman's life he accompanied him to Marienbad and elsewhere. There are several references in Mr. J. A. Spender's *Life* of the Prime Minister to this devoted medical adviser and good friend. It is related how, one night in Paris, Campbell-Bannerman had an alarming heart attack, and there was difficulty in securing medical attendance. The attack passed off, but Campbell-Bannerman's private secretary, Mr. Arthur Ponsonby, decided that to have a sick Prime Minister on his hands in a foreign capital was too great a responsibility, and in the morning telegraphed to Burnet, who came over at once and took his patient to Biarritz. Burnet was knighted in 1908, and created K.C.V.O. in 1917.

He was not a voluminous author, but his one book, first published in 1890, attained great popularity, and ran quickly through five editions. It was entitled *Foods and Dietaries: a Manual of Clinical Dietetics*, and it is characteristic of his methods that it gives detailed directions for dieting in a large number of conditions, with suggested menus for every meal. In 1890 he became physician to the London Life Association. This appointment he held for twenty-seven years, when he became a director. He was president of the Section of Medicine at the Annual Meeting of the British Medical Association held at Portsmouth in 1899.

WALTER C. STEVENSON, B.A., M.D.

Surgeon and Consulting Radiologist, Steevens' Hospital, Dublin

We regret to announce that Dr. Walter C. Stevenson, the Dublin radiologist, died at his residence in Lower Baggot Street, on February 19th, from pneumonia following influenza.

Walter Clegg Stevenson was born at Calcutta in September, 1877. He received his early education at St. Paul's School, and the High School, Dublin, and entered Trinity College in 1895, graduating B.A. in 1898, M.B., B.Ch. in 1900, and proceeding M.D. two years later. He entered the R.A.M.C. as a lieutenant in 1901, winning the De Chaumont Prize at Netley, and serving in the South African war. He resigned his commission in order to take up practice and research in Dublin. His successful work in connexion with radium treatment is well known to the medical profession in Europe and America. He was the first to apply radium in needles for the treatment of cancer. During the war he did much valuable work for the British War Office in connexion with radium research, and in 1919, having obtained a supply of radium from the Royal Dublin Society, he and Professor Joly, president of the society, carried out valuable investigations in Dublin. Dr. Stevenson's method of radium treatment was used by him during the period of the war on more than 2,000 patients, about half of whom were suffering from cancer. It was in 1914 that Professor Joly first suggested to Dr. Stevenson that the best way to use radium would be by frequent applications in small quantities. Mr. Richard Moss added further valuable suggestions, and their treatment was so successful that leading members of the medical profession travelled from London and Paris to the Royal Dublin Society to see the work that was being done by them.

Dr. Stevenson was a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England, surgeon to Dr. Steevens' Hospital, Dublin, and to the Incorporated Orthopaedic Hospital of Ireland. During the past twelve years his professional standing had risen to a remarkable degree, and his research work and medical knowledge gained him much admiration from his colleagues and from the general public. He was consulting surgeon to the Ministry of Pensions, radium consultant to the Rotunda Hospital, a Fellow of the Royal Academy of Medicine in Ireland, and honorary secretary to the Irish Centre of the St. John Ambulance Association. He was the author of many books and papers on radium treatment. At a meeting of the council of the Royal Dublin Society the following resolution of condolence was passed:

> The council wish to place on record their sense of the loss which the society has sustained by the premature death of Dr. Walter C. Stevenson. The loss applies more especially to the work of the Irish Radium Institute, in which work for the alleviation of suffering Dr. Stevenson took a foremost part. His work on this branch of medical science was not only that of the practitioner, but was more especially concerned with his solution of the problem of securing uniformity of radiation in any accessible region of the human body. The now well-known "needle method" was Stevenson's invention. From testimony received from all parts of the globe this method has been of incalculable value. Its importance in medical science is established beyond doubt, and Stevenson's name will be imperishably connected therewith. In the forthcoming bicentenary account of the history of the society the reference to this part of the society's work for mankind is emphasized, and Dr. Stevenson's connexion therewith is, of course, fully recognized.

Dr. ISRAEL FELDMAN, jun., who died on February 11th, aged 38, received his medical education at the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1915. After acting as assistant medical officer to Whipp's Cross Hospital for a few months, he entered the R.A.M.C., serving with distinction throughout the war and being mentioned twice in dispatches. On demobilization he resumed his work at Whipp's Cross, where he was soon appointed first assistant. In 1922 he graduated M.B., B.S., and started general practice at Golder's Green. Dr. Feldman was a very able and enthusiastic practitioner, of amiable disposition, and devoted to his work. He was a great lover of the open air, and for his young patients organized classes in physical training, which were held in his garden. His loss is deeply mourned by all those with whom he came in contact.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on February 20th the following medical degrees were conferred:

M.B., B.CHIR.—G. L. Robinson, J. H. Hopper, T. C. J. Evans, W. V. Boyle.
M.B.—E. T. O. Slater, H. D. B. Kelly.
B.CHIR.—M. S. M. Fordham, G. N. Grose.

UNIVERSITY OF LONDON

LONDON HOSPITAL MEDICAL COLLEGE

The Liddle Triennial Prize offered in 1929-30 has been awarded to Dr. William Evans.

UNIVERSITY OF LEEDS

Dr. J. O. Terry has been appointed demonstrator in pathology.

UNIVERSITY OF BRISTOL

The dissertation for the degree of M.D. submitted by A. E. Hayward Pinch has been approved by the Board of Examiners.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Museum Demonstration

The spring course of museum demonstrations in the theatre of the College will commence on Friday, March 6th, when Sir Arthur Keith will discuss the nerve supply of the alimentary tract and the nature of Auerbach's plexus. On March 13th he will demonstrate specimens illustrating the

anatomy, physiology, and pathology of the oesophagus, and on March 20th the anatomy and nerve supply of the diaphragm. On March 9th Mr. C. E. Shattock will demonstrate specimens illustrating diseases of the colon and rectum, and on March 16th he will discuss affections of the kidney. The series will be brought to a close on March 23rd, when Mr. Reginald T. Payne will demonstrate pathological specimens relating to diseases of the gall-bladder and extra-hepatic biliary passages. The demonstrations, which commence at 5 p.m., are open to advanced students and medical practitioners.

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel James Hickman, R.A.M.C. (ret.), died on December 18th, 1930, aged 75. He was born on September 26th, 1855, and was educated at Queen's College, Belfast, graduating as M.A. in the Royal University of Ireland in 1877. He took the L.R.C.P. and S.Ed. in 1880, and subsequently the D.P.H.Camb. in 1888. Entering the Army as surgeon on July 29th, 1882, he became lieutenant-colonel after twenty years' service, and retired on January 20th, 1904. He served in the Burma campaigns in 1886, receiving the Indian frontier medal with a clasp; in West Africa, in the Gambia campaign of 1892, and took part in the attack on, and capture of, Toniataba, gaining the African medal with a clasp; in the Ashanti expedition of 1895-96 (star), and in the operations at Sierra Leone in 1898-99 (clasp); and in the South African war in 1899-1900, when he took part in the actions at Spion Kop, Tugela Heights, Vaal Krantz, and Pieter's Hill, and in the relief of Ladysmith, receiving the Queen's medal with two clasps.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons was occupied this week with Supplementary Estimates. The Unemployment Insurance Bill was read a third time.

The text of the Nursing Profession (Hours and Wages) Bill has been issued. The Bill was introduced by Mr. Brockway on December 10th, 1930, and was down for second reading on February 26th. It is not expected to make progress this session. The Osteopaths Bill and the Hospitals (Relief from Rating) Bill were also formally set down for second reading this week.

The Pharmacy and Poisons Bill still awaits second reading in the House of Lords.

Cerebro-spinal Fever

Replying to Mr. Hacking on February 19th, Mr. GREENWOOD said that he was advised that an increase in the number of cases of cerebro-spinal fever, or spotted fever, was usual in the early months of the year, especially when influenza was prevalent. Local authorities and their medical officers of health were alive to the importance of urging precautions to prevent the spread of this disease. Mr. Greenwood stated that 272 cases of cerebro-spinal meningitis among civilians had been reported during the eleven weeks ended February 14th. There had been 79 cases of this disease reported recently in the West Riding of Yorkshire. The deaths could not yet be stated. Such preventive measures as were practicable were being used. Action taken by his Department included the close observation of reported cases of this disease, and the giving of advice, on request, to local authorities and medical officers of health on the isolation of patients and any practicable preventive measures. If necessary, visits were paid by medical officers of the Department to districts affected. The type of the prevalent organism was studied in the laboratory by the pathologists of the Department, who worked in co-operation with the pathologists of the Army, Navy, and Air Force. It was well established that overcrowding of persons in barracks, schools, and other residential institutions favoured the spread of meningococcus infection. The existence of overcrowding in such circumstances would be investigated in any district affected, but no notable example of such overcrowding had been discovered during the present prevalence of this disease.

Mr. G. H. HALL told Sir H. Cayzer, on February 19th, that one case of spotted fever had occurred at Eastney Barracks, Portsmouth. No outside residents were permitted to attend any Divisional entertainment, and no football, hockey, or shooting matches would take place either at home or away.

On February 23rd Mr. MONTAGUE informed Mr. Groves that twelve cases of cerebro-spinal meningitis, of which six proved fatal, had recently occurred among Royal Air Force personnel stationed at Uxbridge. Eleven of the twelve men concerned had been vaccinated, but none had been inoculated. The dates of vaccination ranged from September 30th, 1930, to January 20th, 1931.

Mr. SHAW, on February 24th, told Lieut.-Colonel Heneage that the usual precautions to combat the outbreak of cerebro-spinal meningitis had been taken throughout the Army with regard to ventilation and prevention of overcrowding. Carriers were being searched for and immediate and remote contacts were being watched. In Aldershot, where rather special conditions obtained, special orders had been issued reducing indoor gatherings to a minimum. He was acting in concert with the civil authorities. With regard to investigations of the cause of the disease, the type of prevalent organism was studied in the laboratory by the Army pathologists, who worked in co-operation with the pathologists of the Navy, Air Force, and Ministry of Health.

Mr. SHAW also told Lieut.-Colonel Heneage that in England and Wales the published figures for the civil population showed a smaller ratio per 1,000 for cerebro-spinal meningitis than was shown for the troops. In regard to Scotland, the reverse was the case, but he was not sure that the figures were on a strictly comparable basis. The incidence of the disease was so spread that there were no grounds for connecting it with any particular type of barrack room. No barracks in the Aldershot Command had been condemned. The minimum cubic space allowed for British troops at Home Stations was 600 cubic feet a man.

Lieut.-Colonel HENEAGE asked whether, having in view the statement made by the Minister of Health that the disease was due to overcrowding, Mr. Shaw would pursue investigations on the types of barrack room. Mr. SHAW said that he would do so. Sir R. HUTCHISON: Will the right hon. gentleman make inquiries as to the percentage in each rank affected? Mr. SHAW: I am anxious to get all the information possible on these matters, and I will also make inquiries with regard to that question.

Mr. SHAW, replying to Mr. Freeman on February 24th, said that up to February 23rd the number of cases at Aldershot during the present outbreak of cerebro-spinal meningitis had been 13 (including a civilian nursing sister), of which 8 had proved fatal. The cause of the outbreak had not been ascertained. Twelve of the patients had been vaccinated, one within a week, one within a month, and the remainder from seven months upwards. Only one patient had been inoculated, and the inoculation was more than three years ago.

Asbestosis and Silicosis

On February 19th Mr. CLYNES stated that he had received a report from the senior medical inspector of factories concerning the death of a woman from heart failure following bronchial pneumonia accelerated by asbestosis. A draft scheme of compensation for this disease was issued last month, with a draft of the proposed medical scheme by which a medical board would be set up to deal with all cases of silicosis and asbestosis throughout the country. These draft schemes were now under consideration by employers' and workers' associations. He was impressed by the urgency of the question, and hoped to reach a final settlement by the end of next month.

Replying to Mr. Morley on February 19th, Mr. CLYNES said that the effects on the lungs of various dusts, including coal dust, were being investigated by an expert committee of the Medical Research Council. This committee was pursuing various lines of research, but the problems were complicated, and considerable time must elapse before definite conclusions could be reached. In reply to another question, Mr. Clynes said that the Various Industries (Silicosis) Amendment Scheme, which amended the definition of "silica rock," came into force on February 1st.

Mental Hospital Laboratories.—Replying to Mr. Kinley on February 19th, Mr. GREENWOOD said that in some areas the local authority had provided a central laboratory for mental hospitals belonging to it. It was hoped, without prejudice to the principle of each hospital having a laboratory of its own, that such centralization might be developed elsewhere, particularly where the laboratory service could be based on the medical school of a university. It was not intended to attempt to set up a single central unit for this purpose.

Housing.—Replying to Major Nathan on February 19th, Mr. GREENWOOD said he did not consider that setting up a Royal Commission or a Departmental Committee would accelerate either the provision of new houses or the clearance of slums. Mr. Greenwood told Sir Kingsley Wood that the London County Council's programme for the next five years was 33½ per cent. more than for the last five years, but he was not satisfied that that was the best the Council could do.

Welfare of Coal Miners.—In the House of Commons, on February 17th, Mr. SHINWELL moved the second reading of the Mining Industry (Welfare Fund) Bill. He said that the Miners' Welfare Fund had been established for a period of ten years, which expired at the end of last year, and it was necessary to ask the consent of the House to proceed with the Fund for another five years. The Fund had provided drying rooms and shelters at the pithead, and in some cases drinking-water underground. Provision had been made for erecting hospitals and the endowment of these institutions in fifty-six schemes. These were costly propositions. There had also been thirty-seven schemes for the provision of convalescent homes. There was general approval of these institutions. There were thirty-one schemes for district nursing services and seventy-one ambulance services. Excellent work was being done in safety research by the Safety Research Board associated with the Mines Department. From the Miners' Welfare Fund approximately £50,000 had been devoted annually to research. The Bill was read a second time.

Sickness Benefit Claims.—Mr. GREENWOOD told Mr. Rhys Davies, on February 23rd, that no precise information was available in regard to the effects of the influenza epidemic on the applications for funds to meet claims for benefit. The applications in January did not show any considerable variation in amount, but further applications now being received indicated a serious increase in the claims for benefit during the last three weeks that might be due to influenza.

Finance of Health Insurance.—In reply to Mr. G. Macdonald on February 12th, Mr. GREENWOOD said that in 1928 employees' contributions to health insurance amounted to £12,600,000, and £32,300,000 was paid in benefits. The figures for 1929 were £12,700,000 in contributions and £34,500,000 for benefits, and in 1930 £12,800,000 in contributions and £32,550,000 in benefits.

Royal Veterinary College.—Dr. ADDISON told Mr. Ormsby-Gore, on February 12th, that it had been unanimously recommended that the Royal Veterinary College should be rebuilt on the present Camden Hill site. That recommendation had been accepted both by the Government and by the Governors of the College. The Government contribution of £150,000 was therefore offered with a view to reconstruction on the site. He did not wish to be considered absolutely bound, but understood that the committee's report was unanimous on the point.

Indian Medical Service.—Mr. BENN, on February 16th, told Major Pole that the contemplated establishment of the Indian Medical Department reserve of sub-assistant surgeons, the formation of which had been sanctioned by the Government of India, was 150 in the first instance.

An All-India Medical Council.—Mr. BENN also informed Major Pole, on February 16th, that the Government of India had reported, on January 27th, that the draft of a new Bill for the establishment of an All-India Medical Council was nearly completed.

Notes in Brief

Mr. Dalton reports that eleven European States have not yet ratified or acceded to the Geneva Gas Protocol.

The first report of the Scottish Advisory Committee on Rivers Pollution Prevention has just been issued. The committee has not yet undertaken an examination of the Clyde.

Medical News

The Harveian Lecture before the Harveian Society of London will be delivered by Sir Percy Sargent at 11, Chandos Street, W.1, on Thursday, March 19th, at 8.30 p.m. The subject will be "The romance of the pituitary gland." At a meeting to be held on May 14th, Dr. Donald Hunter will open a discussion on indications and methods of treatment in calcium therapy. As already announced, the centenary celebrations of the Society will will be held from June 11th to 13th.

At a meeting of the Royal Sanitary Institute, to be held on Friday, March 6th, in the Guildhall, Swansea, discussions will be opened on "The rheumatic child," by Mr. H. R. Tighe, F.R.C.S., and on "Housing," by Dr. J. M. Morris. The chair will be taken at 3 p.m. by Dr. Charles Porter.

The National Institute for Industrial Psychology will *hold a conversazione at Aldwych House, Aldwych,* W.C.2, on Thursday, March 19th, at 8.45 p.m. Sir Frederick Hopkins, P.R.S., vice-president of the Institute, will receive the guests.

The new wing for private patients at the Central London Ophthalmic Hospital, Judd Street, W.C., will be opened by Her Highness Princess Marie Louise on Thursday, March 5th, at 3.30 p.m.

Mrs. Philip Snowden is giving an "At Home" at 11, Downing Street, on Tuesday, March 3rd, in support of the rebuilding appeal on behalf of the London Temperance Hospital.

The secretary of St. John's Hospital for Diseases of the Skin, Leicester Square, asks us to state that the out-patient department is open daily at 1.30 p.m. and 5.30 p.m. (Saturdays at 1.30 p.m. only). Much inconvenience has been caused to patients, especially those who have come from a distance, who have been advised by their doctors to attend for treatment in the morning.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 68. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1. The list of special courses arranged for 1931 is now available.

The next series of lectures and demonstrations on tropical hygiene for men and women outside the medical profession proceeding to the Tropics will be given by Lieut.-Colonel G. E. F. Stammers, from March 18th to 27th. Full particulars can be obtained on application to the secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

The Medical Society of the Mediterranean Coast has arranged a tour from March 29th to April 13th, which will include visits to Cannes, St. Raphael, St. Juan-les-Pins, Grasse, Nice, Cap Martin, Mentone, Monaco, and Cap Ferrat; there will be subsidiary excursions to Corsica, the Alps, and Italy. Fuller particulars of this tour can be obtained from the Federation of the Health Resorts of France, Tavistock House North, Tavistock Square, W.C.1.

King Edward's Hospital Fund for London has received from the Nizam of Hyderabad, through Sir Akbar Hydari, a donation of £2,000, as a token of his gratitude for the personal interest taken by His Majesty the King in the work of the Round Table Conference, and in that of the Hyderabad delegation.

The Gifford Edmonds prize of £100, awarded every two years, is offered for the best essay on radiant energy as (*a*) a pathogenic and (*b*) a therapeutic agent in ophthalmic disorders. It is open to any British subject holding a medical qualification. Preference will be given to original work rather than to compilations from the writings of previous observers. Essays must be sent in not later than December 31st, 1932. A leaflet giving full particulars may be obtained from the secretary, Royal London Ophthalmic Hospital, City Road, E.C.1.

The Home Office gives notice that the Secretary of State proposes, after the expiration of forty days from February 20th, to make new Regulations under Section 7 of the Dangerous Drugs Act, 1920, amending the Dangerous Drugs (Consolidation) Regulations, 1928. The effect of these is to exempt from the application of the Dangerous Drugs Regulations five preparations containing diacetylmorphine (heroin), which the Health Committee of the League of Nations has found cannot give rise to the drug habit on account of the medicaments with which the diacetylmorphine is compounded in them. Draft copies of the new Regulations can be obtained on application to the Under Secretary of State, Home Office, Whitehall, S.W.1.

The American Association for the Study of Goiter again offers an award of 300 dollars for the best essay based upon original research work on any phase of goitre presented at its annual meeting in Kansas City, April 7th to April 9th, 1931. Competing manuscripts must be in the hands of the corresponding secretary, Dr. J. R. Yung, Rose Dispensary Building, Terre Haute, Ind., not later than April 1st. Manuscripts arriving after that date will be held for the next year or returned at the author's request.

The January issue of the *Leprosy Review*, the quarterly publication of the British Empire Leprosy Relief Association, contains an article by Dr. J. L. Maxwell on the menace of leprosy in Manchuria, and the first of a series of reports, by Dr. R. G. Cochrane, on the leprosy situation in East and Central Africa. The growth of a leper therapeutic settlement at Ho, on the Gold Coast, is described by Dr. F. H. Cooke, who pleads for the extension of this method of limiting infection and providing lepers with a happy and useful existence. A note by Dr. Janet Murray, on work in Tanganyika, mentions the inadvisability of compulsory segregation. The *Leprosy Review* can be obtained from the offices of the Leprosy Relief Association, 29, Dorset Square, N.W.1, price 2s.

The *Urologic and Cutaneous Review* for February contains a symposium on certain phases of syphilis, in which 110 experts from various countries contribute their views as to the incidence of the disease since the war, the change in the age at which infection takes place, the prevalence of neurosyphilis, and the development of immunity against syphilis in the more advanced populations of the world.

The 117th to 119th volumes of *Deutsche Zeitschrift für Nervenheilkunde* are dedicated to Professor Max Nonne of Hamburg on the occasion of his seventieth birthday.

The fourth Congress of the German Association for the Investigation of the Circulation will be held at Breslau, on March 9th and 10th, when special attention will be devoted to digitalis therapy in all its aspects. Further information may be obtained from Professor Bruno Kisch, Lindenburg, Lindenthal, Cologne.

A medical faculty, at which 150 students have been enrolled, has recently been opened at Samarkand in Turkestan.

An institute of serology and venereal prophylaxis has recently been created at the Toulouse Medical Faculty.

An institute of dietetics has been opened at the Pazmany-Peth University at Budapest under the direction of Professor A. v. Soóz.

Dr. Maurice Genty, editorial secretary of the *Progrès médical*, has been appointed librarian of the Académie de Médecine.

The King has approved of the retention of the title of "Honourable" by Dr. Richard Arthur, who has served for more than three years as a member of the Executive Council of the State of New South Wales.

The King has appointed Dr. Donald P. Wailling to be an official member of the Executive Council of the presidency of the Virgin Islands.

Trichinosis has recently been made a notifiable disease in Saxony.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Majorca

"A. W." writes in reply to "C. M.'s" inquiry. I can inform him: (1) there is no public water supply in Majorca. Each house has either its spring water well, or, more generally in the towns, as in Palma, its well of rain water collected from roofs, etc. Many of the wealthier class allow the poorer neighbours to have access to their cistern. Obviously this system is not without its risks of pollution. (2) Mosquitos and flies are only troublesome between May and November. (3) The temperature is changeable in the winter months, with cold winds after sunset.

"J. M." writes: All the hotels in Majorca frequented by visitors have a water-borne system of sanitation; the sanitary accommodation is satisfactory. I believe the water in the hotels in Palma and Pollensa Port is safe to drink; milk should be boiled; bottled mineral waters are cheap. During the winter months flies and mosquitos are not in evidence. Near Pollensa there is a good deal of swampy ground, and near Alcudia rice is cultivated. Enteric fever is not uncommon among the natives, but very rare among visitors. I consider the climate from October to April is eminently suitable for patients who suffer from recurring chest colds or rheumatism. There are windy, wet, and cold days, but these are infrequent; for the most part the weather is dry and sunny, and the high mountains along the north coast are a protection against cold winds. There are no great extremes of temperature; the daily variation rarely exceeds 10° F., and is usually less than 5°. The hotels in Palma and its suburbs have central heating, and so have the two in Pollensa Port with which I am acquainted. As regards the advisability of sending actual invalids to Majorca, it should be remembered that there is no English medical man in practice there, or was not a year ago. The hotels are clean and comfortable, and charges moderate, though higher than formerly. A year ago the charges in Palma and its suburbs varied from 15 pesetas to 25 pesetas a day (7s. 6d. to 12s. 6d.). In Soller and Pollensa Port they were less. Chamberlin's *Guide to Majorca* is full of information; it is published by the "Fomento de Turismo," Palma, and may be obtained from the Spanish Travel Bureau, 173, Piccadilly, W.

His Excellency the Spanish Ambassador has been good enough to send us some printed particulars of recent date about the Balearic Isles, which we have forwarded to our correspondent, "C. M."

Prevention of Boiler "Scale"

"S. S." would be glad to know of any personal experience in the domestic use of methods (not including "water softeners") for the prevention of the deposition of "fur" or "scale" in hot-water boilers and pipes. One form of such apparatus referred to is known as an "activator," and is said to be radio-active and without chemical action.

Assimilation of Inorganic Salts

"S. M. W." (Manchester) asks for references to experimental work, or any reliable statement based on such work, which shows to what extent inorganic iron, calcium, phosphorus, etc., and their salts are assimilated when administered by mouth to human beings.

*** A very large amount of research has been done on the absorption of iron, and also on the absorption of calcium and phosphates from the foods. The older work is vitiated by ignorance (1) of the importance of liver and stomach extracts in regulating the formation of blood, and (2) the control of calcium absorption by vitamin D. Sherman, *Chemistry of Food and Nutrition* (New York, third edition, 1927), and Lusk, *Science of Nutrition* (Saunders, fourth edition, 1928) give general accounts of these problems. The absorption of iron was dealt with in a long series of papers by Whipple in the *American Journal of Physiology* (1920, liii, 151; 1925, lxxii, 395). A recent article on calcium metabolism, by Percival and Stewart, appeared in *Physiological Reviews* (1928, viii, 283). The absorption of calcium and of phosphates is a peculiarly difficult problem; it is controlled by several factors, such as the relative quantities of calcium and of phosphates, the reaction of the gut, and the supply of vitamin D.

The Heart after Artificial Respiration

"ENIGMA" writes: An apparently strong, healthy man died under an anaesthetic given for a small groin operation just as the clips were being fixed. Artificial respiration was continued for fifty minutes, but without avail. At the post-mortem examination the heart was somewhat "ballooned" in shape, being dilated and emptied of blood, while the muscles were normally firm. Is such a condition sufficient to justify one concluding that the heart was at fault, or was the condition due to the effects of a good heart making a terrific struggle and eventually collapsing? After exercise we all know that as the result of increased exudation the lymphatics are fuller and help to make the heart larger and heavier, while, as Starling pointed out, an extra exertion is accompanied by greater dilatation. Personally it seems to me far more reasonable to think that the anaesthetic had disturbed the surface tension of the blood corpuscles beyond its capacity for recovery, so that a toxaemic condition ensued due to abnormal metabolic products introduced into the blood. A toxaemia of this sort would tend to raise the blood pressure and give rise to a greatly added strain to the heart. Deaths of this sort seem to emphasize the necessity for a very full and systematic examination of the heart in every patient before an operation, and for the recording of all the facts found.

Income Tax

Motor Car Allowance

"W. S." bought a 14-h.p. car in 1925 for £575; he has had no allowance for depreciation, because "the income tax inspector always replied that I should be allowed in full on replacement." In February, 1931, he bought a second-hand car for £350. What can he deduct?

*** The appropriate deduction on the replacement basis is restricted to the actual out-of-pocket expenditure—namely, £350 less the allowance for the old car. As this amount is less than the original cost to "W. S." of the old car, it would have paid him better if he had persisted in his depreciation claims in the past. In all the circumstances, and particularly if there was any dissuasion from that claim by the inspector, we suggest that "W. S." should point out the fact that he is losing on the basis which he was advised to take, and ask for such modification of the present assessment as will put him into the position he would have been in if he had received the depreciation-cum-obsolescence allowance.

Temporary Lectureship—Expenses

"RETIRED" was asked by a friend to deliver a course of lectures for him in a town a considerable distance from that in which he resided. He received a sum of £125 "in compensation for the extra expense involved," to cover the special expenses of board and lodging, travelling, etc. Is he liable on the full amount of £125?

*** This is a difficult case, because so much turns on the precise arrangement made with regard to remuneration, and, between friends, it was probably informal. If the terms arranged were simply that "Retired" was to receive £125 for the service rendered and was to pay the special expenses thereout, then we fear that he is, under legal decisions dealing with "expenses" incurred in connexion with appointments, liable on the full sum. If, on the other hand, the agreement was, for example, that he should receive £75 as remuneration and £50 as an allowance towards his expenses, he would be liable on the £75 only. In either case, of course, "Retired" would receive £125 and pay his expenses, but there is a definite legal distinction, and in the second case the £50 would not come within the scope of the income tax Acts. The onus of proof is on "Retired," but perhaps some assistance can be derived from correspondence that may have passed before the work was accepted.

LETTERS, NOTES, ETC.

Treatment of Tetanus

Colonel C. C. MURISON, I.M.S. (ret.), writes: Dr. J. H. Grove-White's memorandum on the treatment of tetanus in the *Journal* (November 15th, 1930, p. 821) has encouraged me to publish my experience of the treatment of tetanus in India. The method stated below, with necessary modifications in certain cases, has usually been adopted and found to be most effective. The failures have been almost *nil*; these have invariably occurred in cases which have come under treatment very late. Serum treatment is given as soon as possible after admission—3,000 units intravenously and 1,500 units subcutaneously. On the second day 1,500 units intravenously and 1,500 units subcutaneously, and on the third and subsequent days for about four, five, or six days, till the spasms cease, 1,500 units subcutaneously are given. Additional treatment consists of subcutaneous injections of 1/4 grain of morphine and 1/100 grain of hyoscine hydrobromide (morning and evening for five or six days till there is complete relaxation of the muscles), and, orally, 15 grains of chloretone dissolved in liquid paraffin thrice daily till the spasms have ceased.

Treatment of Hyperthyroidism

Dr. K. L. S. WARD (Brasted) writes: In October last year I had a patient suffering from hyperthyroidism, with the usual symptoms of rapid pulse, exophthalmos, etc.—a true Graves's disease. In the treatment, *x* rays, Lugol's solution, quinine, digitalis, bromides, rest, and vitamins, were prescribed without benefit, but when oedema supervened and the condition was approaching that of heart failure, something fresh had to be tried. The patient craved for and took large quantities of starches, but there was no glycosuria. Assuming that this patient was unable to use his carbohydrate at some point in his metabolism, I instituted the following routine: first he was given 5 minims adrenaline (1 in 1,000) hypodermically, followed by 6 c.cm. glucose intravenously, and then by 20 units of insulin. In addition to this I gave him, on alternate days, a diet of excessive starch, with half an ounce of dextrose, four times daily. Under this treatment he is much improved. I have never before found any drug of much use in similar cases.

The Common Moustache Brush

Sir HARRY BALDWIN writes: Cannot something be done to cause barbers to amend some of their habits? The particular offence I am now alluding to is that of brushing the moustache of one customer after another with a small moustache brush. Yesterday I was subjected to this treatment, and now, within twenty-eight hours, I am suffering from one of the most acute "colds in the head" I have ever had. I fully believe the infection was propagated to me in this way. The brush had a most foul smell. At a time like this of epidemics of influenza and acute rhinitis it seems a certain way of spreading infection.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 46, 47, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 67.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

183 Auricular Fibrillation in Heart Disease

W. M. FOWLER and C. W. BALDRIDGE (*Amer. Heart Journ.*, December, 1930, p. 183) report ten cases in which auricular fibrillation was the only symptom of cardiac disease. The ages of the patients ranged from 17 to 34, and all except two were under 30. In seven cases the fibrillation was paroxysmal, while in three it had persisted for periods of two weeks, five months, and two and a half years respectively, sinus rhythm being restored by quinidine when it would otherwise probably have persisted. A post-mortem examination was eventually performed on the patient who had had fibrillation for two and a half years, and the heart was reported as being grossly and microscopically normal. In one case the fibrillation was attributed to the removal of wax from the ear; in another to exertion; in four to alcoholism; in one to carbon monoxide; in one to ether and nitrous oxide anaesthesia; and in two patients to having been engaged in work at petrol stations. The authors have collected 35 cases from the literature in which fibrillation was the only sign of cardiac damage, and discuss the etiology. Abdominal disease and alcoholism were the most common exciting causes; in the first group it is suggested that a reflex stimulation over the vagus contributed to the production of fibrillation.

184 Induction of Diuresis in Nephritis

W. EWIG (*Deut. med. Woch.*, January 9th, 1931, p. 51) states that diathermy applied over the region of the kidneys increases their blood supply and thus causes diuresis. In normal persons he has produced a striking diuresis in this way, there being a direct action on the kidney, as shown by an experiment where the urine was collected from ureteric catheters during diathermy on one side only. Not only is more water excreted, but though the concentration of the urine becomes less, the total excretion of chloride and nitrogen is increased. Some of the results in severe cases of acute nephritis with anuria and convulsions have been most striking, the method used being the application of an electrode measuring 30 cm. square to the abdomen, and one measuring 20 by 15 cm. over each kidney, a 3 to 4 ampere current being passed through for two hours at a time twice daily. Illustrative cases are described where immediate diuresis occurred, the convulsions ceased, and the nephritis cleared up in a few days. In the convulsive cases diathermy can be applied to the head at the same time. The results in subacute and chronic types of nephritis are said to have been much less satisfactory.

185 Chronic Bromide Poisoning

C. P. WAGNER and D. ELIZABETH BUNBURY (*Journ. Amer. Med. Assoc.*, December 6th, 1930, p. 1725), impressed by the incidence of bromide intoxication among psychotic patients admitted to the Colorado Psychopathic Hospital, record observations upon 1,000 consecutive cases in which routine determinations of the bromide content of the blood were made. In 77 the serum showed the presence of bromide in concentrations of 75 mg. per 100 c.cm. and over, and in 44 of these the mental symptoms were due to, and increased by, the bromide. The authors consider that serum concentrations of 200 mg. per 100 c.cm. should be regarded as toxic; the figure should be kept below this point, since in higher concentrations some evidence of toxicity usually manifests itself, taking the form of increased restlessness, hallucinations, and apprehension, with physical symptoms of tremor, speech defect, ataxia, and finally stupor. In concentrations over 300 mg. life may be endangered, and the delirium may mask any underlying psychotic condition. Treatment is mainly supportive and eliminative, the diet and fluid intake being increased. Sodium chloride in 15-grain doses three times daily by the mouth increases bromide elimination. In patients showing evidence of debility and dehydration, however, its administration is undesirable, since it liberates the bromide from the tissues too rapidly for elimination by the kidneys, causing a rise in the blood bromide content, and possibly a fatal exacerbation of the toxic symptoms. Where there is impairment of the excretory or circulatory functions the administration of bromide must be carefully watched, but untoward mental symptoms can be minimized if the physician is on the look out for any exacerbation, or ascertains the bromide concentration in the blood.

186 Prophylaxis of Epidemic Poliomyelitis

E. MORO (*Klin. Woch.*, December 20th, 1930, p. 2383) suggests that when poliomyelitis threatens to assume an epidemic character prophylactic injections should be at once started, consisting not of convalescent serum, which is usually not available, but of normal adult blood or serum. Experimental work has shown that the blood of most adults is bactericidal; it is therefore extremely probable, although not absolutely proved, that it possesses a protective power. It is unknown how long such passive immunity lasts, but on the analogy of measles convalescent serum it would be about four weeks; a second injection would therefore be required at the end of this period. Since children under 5 years of age are most susceptible to poliomyelitis, Moro thinks that the injections might well be confined to children between 6 months and 5 years old. In urban districts where the majority of adults—that is, persons over the age of 15—possess specific protective substances in their blood, at least 20 c.cm. of the parents' blood should be injected intramuscularly. In rural districts in which there is infrequent communication with towns the immunity of adults is at most 50 per cent., and the protective power of the blood of such adults is consequently uncertain. It is desirable, therefore, that in such cases blood should be obtained from adults living in towns. Moro suggests that serum centres should be established, as in the case of measles convalescent serum.

187 Spastic Hemiplegia following Post-Vaccinal Encephalitis

J. DUKEN (*Zeit. f. Kinderheilk.*, November 22nd, 1930, p. 293) records two cases in female infants aged 18 months and 13 months respectively. In the first, convulsions developed on the tenth day after vaccination, followed two days later by right hemiplegia, which disappeared in about a week's time after intravenous and intramuscular injection of 200 c.cm. of the mother's and aunt's blood. Complete recovery ensued. In the second case right hemiplegia developed within a month after vaccination, which had been followed by high fever, though there were no convulsions. No special treatment was adopted, and the hemiplegia became spastic and permanent.

188 Post-Traumatic Mental Symptoms

Dealing solely with mining accidents, M. J. COHEN (*Journ. Med. Assoc. of South Africa*, December 13th, 1930, p. 724) analyses these conditions in 105 cases. Psychoses are rare sequels of mine injuries, while psychoneuroses are common; their etiology here is the same as in any other occupation, the desire for compensation and the abandonment of dangerous work being important factors. The two main nervous affections after trauma are anxiety neurosis and hysteria. The headaches and other head sensations of the non-organic and organic sequels of trauma are differentiated; they have both diagnostic and prognostic importance. In the first, the sensations are subjective, and are due to suggestion and to vasomotor changes; in the second, some actual damage to the scalp,

skull, membranes, or brain may be present. Sometimes an injury to a miner reveals coexisting organic disease, such as syphilis. Treatment of these mental sequels may consist of rest, suggestion, and other forms of psychotherapy. Prognosis depends much on the patient's reaction to the awarding of compensation and his response to treatment. ALICE COX (ibid., p. 728) reports a small series of cases which illustrate some of the types discussed by Cohen.

189 Toxic Diphtheria

A. HOTTINGER (*Schweiz. med. Woch.*, January 3rd, 1931, p. 13) illustrates the great frequency of toxic diphtheria by the fact that out of 796 cases of diphtheria recently admitted to the clinic for infectious diseases at Düsseldorf, 40 (of which 20 were fatal) were examples of this kind. The cases of laryngeal diphtheria numbered only 25, and only 5 were fatal. The attacks were remarkably refractory to large doses of antitoxin, and treatment by convalescent serum alone, or in combination with antitoxin as recommended by Hentschel, was also unsuccessful.

Surgery

190 Intrathoracic Tumours

T. C. DAVISON (*Arch. of Surg.*, Part II, December, 1930, p. 1393) divides intrathoracic tumours into the primary, which may be benign or malignant, and the secondary, which are nearly always malignant. Benign primary tumours include lipoma, chondroma, osteoma, fibropapilloma, and dermoids; they may occur in the mediastinum or in the lungs. They may cause pressure symptoms, and sometimes pulmonary suppuration and sepsis by obstruction of the bronchi. Of malignant intrathoracic tumours, carcinoma is the most frequent, and may be diagnosed by *x* rays and the bronchoscope. Primary carcinoma of the lung may be endobronchial or parenchymatous, the former being the more common. It occurs more frequently in men than in women, chronic irritation being the principal cause, due to the inhalation of irritating substances such as coal dust, gases, and tobacco smoke. It is most common after the age of 60, and about 80 per cent. of cases involve the upper lobes of the lungs. Secondary tumours of the lung are metastases from some distant primary focus; they may be single or multiple, and may grow into large spheroidal masses. The symptoms of cancer of the lung resemble those of tuberculosis, and diagnosis must be made by means of the bronchoscope and *x*-ray examination. Benign tumours of the chest should be removed surgically whenever accessible, and early operation is essential for primary malignant growths. After removal of the tumour-bearing area, healing should occur without infection. The so-called dead space is obliterated by the elevation of the diaphragm, the contraction of the thoracic wall, and possibly by a physiological emphysema of the rest of the pulmonary tissue. In extensive operative procedures on the lung a two-stage operation is advised. In late cases partial collapse of the affected lung, evacuation of secondary abscess, and resection of a large portion of the tumour will give temporary relief.

191 Injection Treatment of Varicose Veins

J. P. COLL (*Med. Journ. and Record*, December 17th, 1930, p. 578) reviews the recent developments in the choice of solutions and technique in the treatment of varicose veins by the injection of hypertonic fluids. The method has distinct advantages over surgical treatment in that the period of incapacity is much shorter, often scarcely interfering with daily duties; it is less painful, cheaper, and gives better cosmetic results. The solutions in general use are: (1) a 20 per cent. sterilized solution of sodium chloride, of which from 2 to 12 c.cm. are injected at various points; (2) a 20 per cent. solution of sodium salicylate, of which 3 to 5 c.cm. are injected; (3) 2 to 12 c.cm. of 75 per cent. glucose, either alone or with 5 per cent. sucrose; (4) a solution of 0.4 gram of quinine dihydrochloride with 0.2 gram of urethane in 3 c.cm. distilled water; and (5) a 1 in 500 solution of metaphen for small veins. The aim is to use a hypertonic fluid which, in contact with the intima of the vein for five minutes, will so thoroughly irritate and destroy the intima as to result in sclerosis. After the affected vein has been defined and brought with prominence by a tourniquet above the knee the injection should be made very slowly with a 10 c.cm. syringe and a 26 gauge needle, care being taken that none of the solution passes outside the vein, a pad of gauze being held over the site of puncture for some minutes to prevent leakage. Contraindications are cardiac and renal disease with venous stasis, obstruction to the deep circulation, arterio-sclerosis, and acute or subsiding phlebitis.

192 Stieda's Lesion

W. F. BAASTAD (*Norsk Mag. f. Laegevidensk.*, December, 1930, p. 1385) records four cases in adult patients, aged 50, 25, 53, and 40 respectively, of the so-called Stieda's lesion, the pathological nature of which is doubtful. The traumatic origin of the condition is obvious, the nature of the trauma being a violent abduction of the knee. Most of the cases are not examined by *x* rays until the end of three of four weeks, when a shadow will be found external to the epicondyle, in some cases above and in others below it. Some authorities maintain that the shadow is due to a metaplastic process connected with rupture of the tendon or ligament, but others have found either a fragment of bone torn from the condyle or a process of bone formation arising from a piece of periosteum which has been torn away by the trauma. In three of Baastad's cases a fracture was detected, in spite of the fact that the *x*-ray examination did not take place until four weeks after the trauma. In one case in which no shadow was found three months after the trauma there had probably been only a rupture of a tendon or ligament, although the nature of the trauma and the symptoms were the same as in the three other cases. All the patients were treated by massage with good results.

193 Treatment of Malignant Tumours with Radio-active Bismuth

According to H. KAHN (*Deut. med. Woch.*, December 12th, 1930, p. 2131), of the heavy metals which have been used in colloidal form in the treatment of malignant disease, bismuth alone becomes selectively distributed in the cancer cells. Instead of giving injections first, followed by radiation of the tumour, he has used a preparation of bismuth previously rendered radio-active (bismuth-isotope Radium E). Human and animal experiments indicate that this bismuth-isotope becomes concentrated in the tumour eighteen times as much as in the corresponding normal tissue. This concentration can also be demonstrated by placing a section of the tumour (after injection of the patient or animal) on a photographic plate in the dark room, when a picture of the tumour ("autoradiogram") can be obtained owing to the blackening of the photographic plate by the radio-active material in the tumour. No serious untoward effects have yet been observed from treatment by radio-active bismuth, and, unlike thorium, it does not damage the blood cells. So far as clinical results are concerned, there is an undoubted influence on tumour growth, but the method is too much in its experimental stage for any final decision.

194 Bilateral Simultaneous Artificial Pneumothorax

V. MONALDI (*Riv. di patol. c clin. della tubercolosi*, December, 1930, p. 1005) records his observations on nine cases of bilateral simultaneous artificial pneumothorax in patients between the ages of 17 and 34. He concludes that in some cases of pulmonary tuberculosis the bilateral procedure may be as valuable therapeutically as unilateral pneumothorax. The tolerance of double simultaneous collapse of the lung in suitable cases in which the treatment is conducted properly is established by a change taking place in the functional and cardio-vascular equilibrium. In cases in which the collapse is exaggerated,

owing to errors of technique or to extensive respiratory or cardio-vascular lesions, insufficiency may develop. Respiratory insufficiency is manifested by exaggerated thoracic movements, increased respiratory quotient, a low alveolar tension of CO_2, and changes in the basal metabolism; while cardio-vascular insufficiency is indicated by fall of the systolic pressure, usually accompanied by diastolic hypertension, arrhythmia, asystole, exaggerated dicrotism, and other changes in the form of the sphygmogram.

195 Tonsillectomy in Acute Cervical Adenitis

H. L. BAUM (*Journ. Amer. Med. Assoc.*, December 13th, 1930, p. 1829) reports a series of 40 cases in support of his view that it is safe to remove tonsils and adenoids during the height of an anterior cervical adenitis, and that such a procedure is to be recommended. The average age of the patients in his series was 3.6 years. All the patients showed acute enlargement of the anterior cervical glands following a combined tonsillar and pharyngeal infection, with soreness and tenderness of the glands, stiffness of the neck, general prostration of varying degree, high and usually irregular pyrexia, leucocytosis and an increase in the polymorphonuclears, and a decrease in haemoglobin. Baum believes that tonsillectomy should be performed in such cases as soon as it is seen that no progress is being made, since early removal of the chief source of infection of the glands is clearly indicated. He has had no unfavourable operative sequels, and for the most part the subsequent improvement was dramatically rapid.

Therapeutics

196 Insulin in Wasting following Cholelithiasis

D. CECCARELLI (*Il Policlinico*, Sez. Prat., November 17th, 1930, p. 1665) reports the beneficial results of insulin treatment in a youth of 18 who lost 3 stone in weight during six months, following cholelithiasis, and in whom tuberculosis and diabetes had been excluded. It is generally thought that such wasting is due to chronic or sclerotic pancreatitis. Other forms of treatment having failed, the patient received 20 units of insulin daily, 10 units being given twenty minutes before the two principal meals. In 45 days the patient gained 32 lb. in weight, after which the treatment was discontinued. In the first five days the patient gained 8½ lb., which the author attributes to an increased retention of water, confirmed also by decrease in diuresis; the subsequent continued increase in weight was probably due to improved assimilation. Adrenaline was administered orally in daily doses of 30 minims owing to the patient's low blood pressure, and also because of its well-known action in preventing hypoglycaemia and reducing diuresis. Five months after the cessation of the insulin treatment the patient was still improving, the increase in weight being maintained.

197 Treatment of Gastric Ulcers by Pepsin

M. LOEPER, M. DEBRAY, L. MICHAUX, and Mlle SAINTON (*Presse Méd.*, October 29th, 1930, p. 1465) have treated a series of 20 cases of gastric and duodenal ulceration by the hypodermic injection of pepsin. In a preliminary series a 10 per cent. solution of pure sterilized pepsin was given in 1 c.cm. doses, but, owing to rather troublesome general reactions, a 10 per cent. solution of pepsin was made up with the addition of sodium benzoate, which eliminated the unpleasant reactions without lessening the efficacy. A standard course of treatment consisted of a first injection of 1 c.cm. into the muscles of the buttock; this acted as a test of tolerance. The following injections were of 2 c.cm., and were repeated three times a week for fifteen doses. Three weeks' rest was then allowed, with a simple but generous diet, after which, if the pains returned, a second similar course was given. The authors were guided by the tolerance displayed by the patient, and by *x*-ray examination as to the frequency and desirability of further courses of injections. The treatment was well borne and the results were very gratifying in 19 patients, most of whom had had previous unsuccessful treatment of different kinds. A detailed table is given of the results of treatment; in it are included two cases of carcinoma which showed little change except disappearance of pain. Among the cases treated by pepsin were 2 ulcers of the lesser curvature, 7 pyloro-duodenal, and 7 duodenal. No other medication was employed simultaneously, and the authors claim that the injections of pepsin must have caused the almost uniform and dramatic amelioration in all the cases except one. They discuss its method of action, and conclude by stating their belief that cases of hyperchlorhydria and ulceration are hypersensitive to pepsin, and that the good effects produced by its injection can be better explained by the hypothesis of hypersensitivity than on any other lines.

198 Yagéine or Harmine

J. DECOURT and A. LEMAIRE (*Paris Méd.*, December 6th, 1930, p. 505) discuss the identity of two alkaloids isolated from the South American creeper yagé, the first in 1923 by Cardenas and the second in 1847 by Fritzsche. Solutions of the salts (sulphate and chlorhydrate) are slightly fluorescent. In man a therapeutic subcutaneous dose of 2 to 3 cg. causes a slight fall in the blood pressure and slowing of the pulse rate, a glycaemia of 10 to 50 cg., and a lowering of the basal metabolism, which may reach 20 per cent. The drug was first used in Parkinsonism by Kurt Beringer. The subcutaneous administration of 2 c.cg. dissolved in 1 c.cm. of water is followed in half an hour by a sense of well-being in the patient. There is diminution of the hypertonicity, permitting of voluntary movements being performed with greater ease and suppleness. The tremors are increased in amplitude and frequency, the latter often being doubled. Generally, post-encephalitic cases of Parkinsonism in the young yield more readily to this drug than examples of the classic disease in the aged; in many cases there may be no change whatever. The therapeutic effect lasts for a few hours only, rarely 24 hours to a few days. Good effects, and no untoward incidents, are reported with daily subcutaneous injections of 2 cg. Beringer also advocates doses of 4 cg. in keratin-coated capsules two or three times a day. Suppositories appear to be more efficacious. Both these methods afford alternatives to the injections for long-continued therapeutic effect.

199 Splenic Extract in Malarial Anaemia

C. HEDERER (*Bull. Soc. de Thér.*, November 12th, 1930, p. 288), who records three illustrative cases, states that the Toulouse school, represented by Remond, Soula, Colombies, Bouisset, Tapie, Pau, and Radji, have for some time emphasized the important part played by extracts of the spleen in regeneration of the blood. In the cases of chronic malarial anaemia reported by Hederer treated by intramuscular injection of splenic extract in the form of a preparation called liposplenine, a progressive and persistent diminution took place in the size of the spleen, there was a marked increase in the number of red cells, and improvement in the general condition was shown by increase of weight and a return of appetite and strength.

200 Serum Treatment of Chronic Ulcerative Colitis

J. A. BARGEN, E. C. ROSENOW, and G. F. C. FASTING (*Arch. Int. Med.*, December, 1930, p. 1039) report successful results in the treatment of chronic ulcerative colitis with an antibody solution obtained by precipitation in ether-water of the specific immune serum of chronic ulcerative colitis. Details of the method are described. Fasting's antibody euglobulin solution was administered deeply and intramuscularly in about 200 cases of chronic ulcerative colitis; the important facts of the first 50 consecutive cases are given, observation having been made for a time sufficient to justify an opinion as to the value of the treatment. Uncomplicated cases are best treated by this process of immunization against the causative

organism; the results are said to surpass those of other methods, including operation and irrigation of the colon with medicated solutions. Since at present it can only be hoped to control the condition rather than to effect a cure, patients who have once overcome an attack should continue to receive the vaccine periodically, but the degree of frequency required is still problematical. The treatment is most useful in the more severe, subacute cases in which it was usual to perform ileostomy; the need for this procedure has been less frequent, and more limited to dealing with complications, since the institution of serum therapy in this disease.

201 Bismuth Subnitrate in Arterial Hypertension

E. J. STIEGLITZ (*Journ. Amer. Med. Assoc.*, September 20th, 1930, p. 842), while admitting that the etiology of arterial hypertension is obscure, stresses the importance of combating the vicious circle of muscular irritation followed by fatigue and increased irritation, and finally resulting in vascular sclerosis. Considering that the action of the usual vaso-dilators is transient, and therefore of little value, he has tried bismuth subnitrate in doses of 10 grains three times a day; the bismuth ion is inactive, the specific action on arterial muscle being due to small quantities of nitrites which are liberated continuously by the action of *B. coli* in the intestine. In 200 unselected patients of all ages treated by this method, he has obtained reduction of the diastolic pressure below 100 mm. in 77 per cent. Of the total number treated, 122 were free from arterio-sclerosis, and 78 suffered from it to some degree. The result of treatment, which extended over a period on the average of six months, is gauged by the "percentage reduction of pressure towards normal for the age." This "percentage reduction" for systolic and diastolic pressures amounted respectively in the arterio-sclerotic group to 39 and 46 per cent., and in the other group to 73 and 105 per cent. The treatment of 120 cases of hypertension associated with pregnancy showed the amenability of such cases to the same treatment, but the association with a definite, if unknown, toxic state makes the pressure reduction of doubtful use, or even dangerously misleading. Stieglitz believes that the breaking of the "vicious circle" over a period of several months is of definite therapeutic value, and he has observed some cases where such a course of treatment has been followed by a continuation of lowered pressure for three to four years. Commenting on the use of bromides and sedatives of the barbituric acid group, he holds that the bismuth subnitrate therapy gives better and more lasting results.

Disease in Childhood

202 Still's Disease

M. TROMBETTI (*Rinascenza Med.*, October 15th, 1930, p. 502) publishes a synthetic account of Still's disease, which he recognizes as a definite entity, differing from other infective forms of arthritis; its origin is as yet unknown. The paper is illustrated by photographs and radiograms of the condition. Usually the disease sets in gradually in young subjects, but may start more abruptly like an acute rheumatism; it differs in not "flying from joint to joint," but tending to become fixed in one or other articulation and in enlargement of the spleen and lymphatic glands. The fever may be of a chronic, protracted type, or be intermittent; each recurrence of fever is associated with fresh joint involvement. Occasionally rashes may occur. Growth is stunted, and as a rule there is marked cachexia and some anaemia, with variable changes in the white cell count. In the early stages the larger articulations are affected, later there is a symmetrical spread to the smaller joints; once started, the disease tends to remain fixed. Owing to the muscular wasting the articular ends appear more enlarged than they really are. Osteoporosis of the epiphyses is common. The enlargement of the lymphatic glands is secondary to the joint infection, and due to the same cause, whatever that may be. Authors are agreed that there is no sign of tuberculosis in these cases, but pericarditis is a fairly frequent epiphenomenon. The disease is essentially chronic, and seldom fatal. Treatment so far seems to be of little avail. Sometimes the onset of some intercurrent affection influences the course of the disease favourably, so that in the absence of any known cure malaria therapy might possibly be worth trying.

203 Treatment of Bronchiectasis in Childhood

R. NISSEN (*Münch. med. Woch.*, October 24th, 1930, p. 1849) considers that many cases of bronchiectasis in children originate in congenitally dilated bronchioles, and that the condition only follows "prolonged pneumonia" comparatively rarely; treatment should therefore aim at compressing these bronchioles. In order to achieve this he plugs the thoracic cavity round the affected lobe with a mixture of paraffin wax, and reports that good results have followed this method. In a child 300 to 400 c.cm. are required, and expectoration ceased completely in a number of cases thus treated; the scoliosis which almost inevitably follows extensive rib resection or artificial paralysis of the diaphragm in a child is avoided. For those cases in which the effect of paraffin plugging is not permanent he advocates lobectomy, remarking that if this is carried out in several stages the risk is not excessive. Among four children treated thus there were no deaths, though among 28 adults the mortality was 10 per cent. Nissen has found pneumothorax treatment disappointing in bronchiectasis. If a low pressure was used the alveoli alone were compressed and not the dilated bronchioles; higher pressure merely displaced the mediastinum, again without affecting the bronchiectatic dilatations.

204 The Measurement of Intelligence in Infants

T. SIMON (*Paris Méd.*, November 1st, 1930, p. 403) records the stages in the mental development of infants, previously defined in collaboration with Binet. At the age of 3 months the infant should follow with his eyes any object held up before him. At 6 months he should turn towards sounds, seeking their origin. At 9 months he should seize an object within his reach in his field of vision. This is, of course, different from the earliest reflex action—namely, the grasping of any object placed in his palm. At 12 months he should recognize articles of food; thus he should be able to tell the difference between a biscuit and a piece of wood of the same shape and colour, by touch or taste, or both. At 18 months he should be able to say "Mama" of his own accord. At 2 years he should walk, ask to go to the lavatory, and obey simple instructions conveyed to him by word and gesture.

205 Circulatory Changes at Birth

Collating the results of several recent investigations, B. M. PATTEN (*Amer. Heart Journ.*, December, 1930, p. 183) concludes that there is no abrupt change in the infantile circulation at birth, there being a sufficient volume of blood in the lungs of the newborn infant for its need until they are sufficiently ventilated. The volume and power of the pulmonary circuit gradually increase until by the end of the first month the new functional balance in intracardiac pressure is established. Under normal conditions the progressive closure of the ductus arteriosus hastens the enlargement of the pulmonary vessels after birth, but there are many cases in which the normal pulmonary circulation has come into being without such a closure, the foramen ovale falling gradually into disuse, and then becoming obliterated. Failure of the ductus arteriosus to close is regarded as a symptom rather than a cause of circulatory dysfunction. Following the increase in the pulmonary circulation, and the closure of the foetal blood passages, there is a gradual increase in the musculature of the left ventricle until it equals that of the right at the age of 3 to 5 months. It has acquired a definite preponderance by the second year, and its full adult relation to the right ventricle by about the seventh year.

Obstetrics and Gynaecology

206 Ectopic Gestation

C. A. BEHNEY (*Journ. Amer. Med. Assoc.*, November 22nd, 1930, p. 1557) reports a series of 167 cases of extra-uterine pregnancy, and concludes that diagnosis depends on the association of a history of amenorrhoea with recurring and consistently localized pain in the lower part of the abdomen, metrorrhagia, signs of pregnancy, and the presence of a typical pelvic mass. Ectopic gestation occurs most frequently between the ages of 27 and 35, and the high incidence of anteflexion of the uterus and of irregularity or delay in the menses suggests the possibility of genital hypoplasia. Pelvic masses were found in 85.5 per cent. of the cases, and ruptured ampullar pregnancy was the commonest lesion. Behney did not obtain evidence of pre-existent pelvic disease sufficiently often to incriminate it particularly; in 80.5 per cent. of the patients there had been no previous pelvic symptoms, but when these had occurred there had often been discovered some abnormality of the adnexa on the opposite side of the abdomen to that where the ectopic gestation had subsequently developed.

207 Fibroma Praevia and Forceps Delivery

BAUX (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, November, 1930, p. 703) describes a case in which a very soft and very oedematous fibroma, about the size of the foetal head, was found in the vagina at the end of the first stage of labour in a primipara aged 22. Extraction by forceps was rendered difficult by repeated interposition of the flaccid tumour between the blades. On the third day the fibroma became gangrenous and was excised without haemorrhage from the cervix, to which it was attached by a broad pedicle. GARIPUY (ibid., p. 704) describes two cases of forceps delivery with fibroma praevia. In the first patient, a primipara aged 39, the fibroma ascended from the pelvis late in the second stage, but, subsequently returning, caused difficulty in manual removal of the placenta. In the second patient the fibroma, from the beginning of labour, gradually gave way to the descending head; there was alarming post-partum haemorrhage. In the case of AUDEBERT and E. ESTIENNY (ibid., p. 705) a fibroma praevia, the size of the fist, was found in the pelvis after forty-eight hours' labour, the cord being prolapsed and the foetus dead. Quite suddenly, as preparations were being made for Caesarean section, the tumour ascended above the pubis, and labour was completed by forceps application to the transversely placed head.

208 Causative Factors in Sterility

S. R. MEAKER (*Amer. Journ. Obstet. and Gynecol.*, December, 1930, p. 749) reports a study of sterility comprising elaborate gynaecological and urological examinations and a thorough investigation of both partners from the medical and endocrinological standpoints. Sterility was found to be due in most cases to the combined influence of multiple causative factors, and the assessment of individual responsibility became a complex matter. It appeared that a considerable number of states, generally depressing and debilitating in nature, might reflect themselves in lowered fertility of the sex cells. Any single one of these states, excepting the comparatively few absolute factors, might not be sufficient to cause sterility; all of them together depressed fertility below the threshold of conception. Among endocrine disorders pituitary disturbances were conspicuously in the majority, and the thyroid failures constituted a small but important minority. Protein starvation appeared to be the chief nutritional error militating against fertility. Obesity was not a cause of sterility, but obesity and sterility were frequently associated as simultaneous results of the same underlying subnormality of metabolic function. In nearly 90 per cent. of sterile matings extragenital conditions of constitutional depression were operative. In more than 90 per cent. of clinical cases there was some division of responsibility between the two partners. Meaker found that such complete investigation pointed the way to adequate treatment, which resulted in a percentage of successes more than twice as great as the average of successes obtained by methods previously employed.

209 Occlusions of the Lumen of the Fallopian Tube

R. E. WATKINS and F. R. MENNE (*Journ. Amer. Med. Assoc.*, November 29th, 1930, p. 1647) have tried to determine the most frequent sites and the extent of occlusions of the Fallopian tubes, and the microscopical appearance of the involved area. Forty-nine tubes were examined, the technique employed being to fill the uterine and tubal cavities with bismuth mixtures under measured pressures ranging from 100 to 250 mm. of mercury. Though occlusions may occur in any part of the tube, the most frequent site is the isthmian portion. The fimbriated end, when not adherent to the ovary, is frequently open, or partially so. Restoration of the lumen depends on the absorption of inflammatory products. Healed abscess cavities and canaliculi are important causes of extrauterine pregnancy. In the present series no tubo-ovarian abscesses communicating with abscess cavities in the ovary were found. The authors remark that operations to re-establish the lumen of the tube should never be contemplated until a definite diagnosis of the location of the obstruction has been made. If the occlusion is at the fimbria, this may be opened by separation, or by resection of a portion. When the occlusion is in the intramural or isthmian portions surgery is unsatisfactory. Conservative measures, with the regenerative processes following eradication of the infection, are the best curative agents, and insufflation, or the injection of fluids through the lumen, may aid in opening the channel. The histology of the condition is described at some length.

210 Adeno-acanthoma of the Uterus

Recording a case of that rare condition adeno-acanthoma of the uterus, A. STEIN and F. TOREK (*Surg., Gynecol. and Obstet.*, December, 1930, p. 856) describe as unique a metastasis in the mediastinum and lung. The married patient, aged 42, presented symptoms and signs suggestive of uterine cancer. After hysterectomy, the entire uterine wall was found to be invaded by carcinomatous tissue. For 2½ years after the operation no evidence of local recurrence was noted. A little more than two years after the hysterectomy the patient complained of gastric pain, loss of appetite, and difficulty in swallowing, and radiographic examination of the thorax revealed a mass in the mediastinum. This was diagnosed as a cyst, but, when removed, it proved to be an adeno-acanthoma of the lung and posterior mediastinum secondary to the earlier uterine growth. The patient made a good recovery from this operation also.

Pathology

211 Renal Insufficiency and Azotaemia

E. BECHER (*Klin. Woch.*, December 13th, 1930, p. 2350) defines two distinct types of renal insufficiency associated with azotaemia. In the first type, which is a circulatory disturbance seen in heart failure and also usually in acute nephritis, the non-protein nitrogen, urea, and uric acid are increased in the blood, but the products of intestinal putrefaction, such as indican, are not increased. There is no change in the colour of the urine unless blood is present, and the specific gravity remains normal or high. In the second type there is a real failure of the renal tubules, which is seen especially in chronic nephritis. In addition to the rise in the blood urea, etc., there is an increase of indican, and often creatinine, in the blood even in the early stages. The skin of the patient's hands and face has a yellowish appearance; the urine is of low or fixed specific gravity (hypo- or iso-sthenuria), and is pale in colour, probably owing to failure of the kidney to convert chromogenic substances into their coloured form.

212 Germicidal Properties in Soaps

Some soaps, such as the oleate and bromo-palmitate, are among the most powerful and rapid germicides known, and certain soaps may play an important part in the body defence against bacteria, having, indeed, a selective germicidal action. A. H. EGGERTH (*Journ. Exper. Med.*, January 1st, 1931, p. 27) has tested two series of sulphur-containing soaps, the α-mercapto and α-disulpho varieties. These were found to possess a powerful and markedly selective germicidal action. In the mercapto series, those with 12 and 14 carbon atoms were the most germicidal; in the disulpho series, the dicaprate, dilaurate, and dimyristate were the most powerful. The optimum number of carbon atoms varied with the test organism. Eggerth finds that the number of carbon atoms in the molecule markedly influences the germicidal action of soaps. Two main factors determine this action: the ability of the soap to make its way into the bacterial cell, and its toxic action on the bacterial protoplasm after it has penetrated. As the number of carbon atoms in the soap molecule increases the toxicity becomes greater, but the penetrative power diminishes. So long as molecular size does not prevent entrance of the soap into the cell, germicidal action will increase with the molecular weight; eventually a point is reached where molecular size prevents cell entry, and germicidal action is diminished.

213 Histological Effects of Liver Diet

TH. FAHR (*Deut. med. Woch.*, January 2nd, 1931, p. 8) summarizes the data obtained from 24 post-mortem examinations performed on cases of pernicious anaemia in 1929 and 1930. In 12 of these liver diet had been given for too short a time to have any effect, the patients having been admitted when moribund, or having died from complications soon after admission. These showed the usual morbid appearances associated with pernicious anaemia. In the other cases, which had responded to liver treatment (as far as the blood picture was concerned), but in which death had followed such conditions as sepsis following spinal cord degeneration and broncho-pneumonia, the typical changes in the heart muscle, bone marrow, liver, and spleen were very slight or absent, showing that these had been influenced favourably by the treatment. One patient, a woman who had exophthalmic goitre in addition to pernicious anaemia, failed to respond to liver therapy; the post-mortem changes were typical of an untreated case. In the author's opinion, cases showing predominantly spinal symptoms have the worst prognosis, and are little if at all influenced by treatment.

214 The Relation of Mild to Typical Small-pox

E. DIEM (*Schweiz. med. Woch.*, December 13th, 1930, p. 1174) inoculated with vaccine lymph a number of persons who had suffered from an attack of mild small-pox eight to nine years previously. Of 45 persons tested, five reacted positively, but the reactions in these cases were estimated as being only about one-fifth to one-third of the intensity of a normal control. On the other hand, patients suffering from varicella, when tested at the height of the rash, or six to nine days after its eruption, gave uniformly a strong positive reaction. It would appear, therefore, that the outbreak of mild small-pox which commenced in Switzerland in 1921 may have been immunologically similar to true small-pox, and that it was entirely different from varicella.

215 Haemorrhagic Lesions caused by Clostridium welchii

M. WEINBERG and N. COMBIESCO (*Ann. de l'Inst. Pasteur*, November, 1930, p. 547) bring evidence to show that such symptoms as haemoglobinuria, haematuria, haemoptysis, and gastro-intestinal and uterine haemorrhages observed in patients infected with *Cl. welchii* (*B. perfringens*) are caused by the toxin secreted by this organism. The lethal dose of dried toxin for guinea-pigs was found to be about 1.6 to 3 mg. When these animals were injected intravenously with doses varying from 2.5 to 12.5 mg. they all developed haemoglobinuria, and this was often followed by haematuria; death ensued in 10 to 24 hours. At the necropsy haemorrhagic lesions were generally encountered in the kidney, liver, spleen, stomach, suprarenal, lung, and heart, and sometimes in the uterus and bladder. Besides these lesions, which were apparently due to the haemolytic toxin, focal necroses were found in the liver, and less often in the kidney, due to the non-haemolytic toxin. As regards the mechanism of the haemorrhages, it appears that the non-haemolytic toxin may produce at the same time a rise in blood pressure and a degeneration of the capillary walls; the vessel ruptures, and allows extravasation of blood to occur.

216 Post-Arterio-sclerotic Pulmonary Lesions

E. MOSCHCOWITZ (*Amer. Heart Journ.*, December, 1930, p. 171) describes the brown induration of the lungs which occurs in forms of circulatory or cardiac disturbance in which there has been hypertension of the pulmonary circulation. This lesion is, he finds, exclusively associated with arterio-sclerosis of the pulmonary vessels, a condition pathognomonic of such hypertension; there is dilatation and thickening of the pulmonary capillaries. Part of the sclerotic process is unquestionably the result of a diminished blood supply, and even of infarction of the affected areas. The pulmonary lesions are exactly similar to those seen in the systemic organs, and especially in the kidney, in hypertension of the greater circulation. Moschcowitz reports a case in which brown induration was found after prolonged asthma. Under observation the patient revealed the transition from a purely functional bronchial asthma to emphysema to a pure clinical example of hypertension of the pulmonary circulation, and finally to death consequent on failure of the right side of the heart.

217 Experiments with Foot-and-Mouth Virus

I. SICHERT-MODROW (*Zentralbl. f. Bakt.*, December 8th, 1930, p. 12) has constructed an apparatus for cataphoresis experiments which he maintains is free from the disturbing influence of diffusion currents. With this apparatus he finds that the foot-and-mouth virus is always negatively charged, in this respect resembling the ordinary bacteria. The same results were obtained with all three types—A, B, and C—of virus. No evidence of an isoelectric zone was apparent, such as was concluded to exist by Olitsky and Boëz. In a second paper (ibid., p. 17) the author records experiments on the resistance of the virus to different temperatures. Working with heparinized guinea-pig plasma and guinea-pig serum, he finds that in the dried state the virus may survive in the ice-chest for 1½ to 2 years. At room temperature the virus retained its infectivity for only 5 to 10 days. A surprising resistance was observed to high temperatures. Dried lymph *in vacuo* survived for 2½ hours at 70° C., and for 3 minutes at 122° C. On the other hand, lymph that had not been previously dried was destroyed very rapidly.

218 Skin Tests in Diagnosis of Allergy Conditions

S. M. FEINBERG (*Journ. Amer. Med. Assoc.*, November 29th, 1930, p. 1665) maintains that sensitization estimations should be considered only as laboratory guides, and that there are many limitations to the value of skin tests in allergy. Negative reactions may be given to substances to which the patient is clinically sensitive, or the converse may be the case; negative reactions frequently indicate an absence of allergy, and many variations have been found when relating the tests to the clinical conditions. Complications, such as infection, mechanical difficulties, and neurogenic factors, may be more important than the allergy. These difficulties may be met chiefly by employing, when necessary, other methods of testing, such as the intracutaneous, subcutaneous, conjunctival, and the nasal; by clinical investigations and elimination diets; by a wide knowledge of the clinical correlation and clinical experience in allergy; and by bearing in mind the possible existence of causes other than allergy.

THE RATIONALE OF THE ACTION OF RYVITA CRISPBREAD IN CERTAIN SPECIAL CONDITIONS

CONSTIPATION

The use of Ryvita Crispbread as a corrective where constipation exists is advocated by an increasing number of the Medical Profession.

The special laxative properties of rye grain are well known. Ryvita is made of pure, crushed, whole-grain rye, which is rich in vitamin B, and the salts of lime and iron and phytates.

The ready digestibility of Ryvita, and the low percentage in it of unconverted starch, ensures against starch fermentation, thus keeping the whole alimentary tract in wholesome condition. The roughage and mineral salts of the bran ensure daily natural evacuation of the bowels.

An Eminent Authority declares:

"Washed wheat bran fed to cows was found to be constipating, indicating that the laxative property of ordinary bran and whole-grain products is dependent not simply upon mechanical irritation, but largely, if not mainly, upon the phytates."

It is not improbable that the vitamin B content of Ryvita has also a stimulative effect upon intestinal movements. Reports of recent dietetic research tend to confirm this view.

Many Doctors testify that Ryvita Crispbread gives excellent results in combating habitual constipation. Ryvita is definitely indicated as an item of the dietary in the treatment of disorders arising from indigestion, constipation, or malnutrition. It is usual to suggest that the patient begin by eating two or three slices of Ryvita with at least one meal each day.

RYVITA

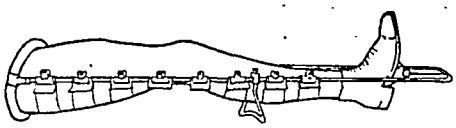
CRISPBREAD

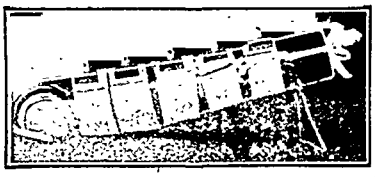
We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

THE RYVITA COMPANY LTD.

785, RYVITA HOUSE, 96, SOUTHWARK STREET, S.E.1

The most modern method of accurate extension and safe transport is provided by





COLLENDER'S SPLINTS

(Patented in the leading countries of the world.)

An evolution of the Thomas splint, preserving all its advantages with many improvements.

Invaluable for Hospital, Emergency, and District Surgeons' work. Indispensable for Mines, Ranches, Lumber Camps, Railways, Shipping Cos., and all places remote from surgical aid. Made of Duralumin, untarnishable, light, and of great tensile strength. All parts interchangeable. Complete splints constructed in a few minutes for limbs of any dimensions. Sufficient members to accommodate ten fractures simultaneously. Supplied in strong fitted case.

Write for full descriptive booklet, post free.

WATSON BAKER COMPANY, WEST END LANE, BARNET, HERTS, ENGLAND

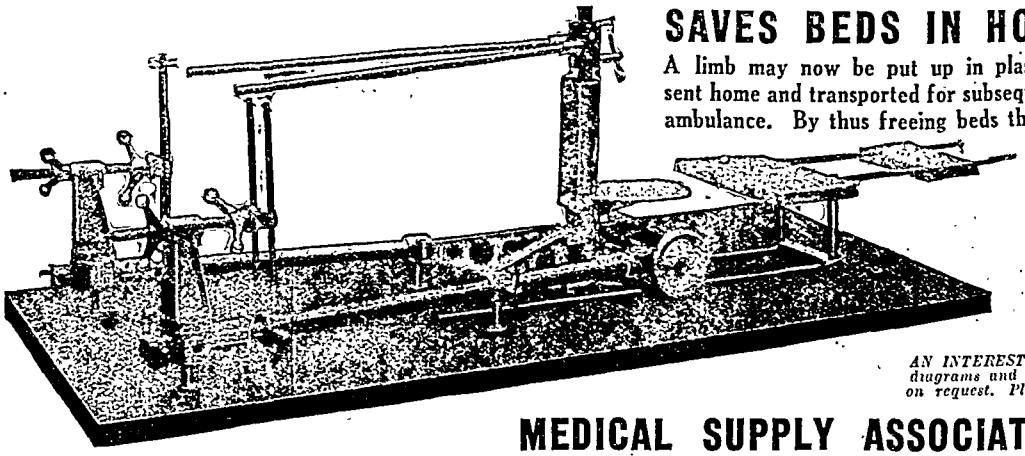
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

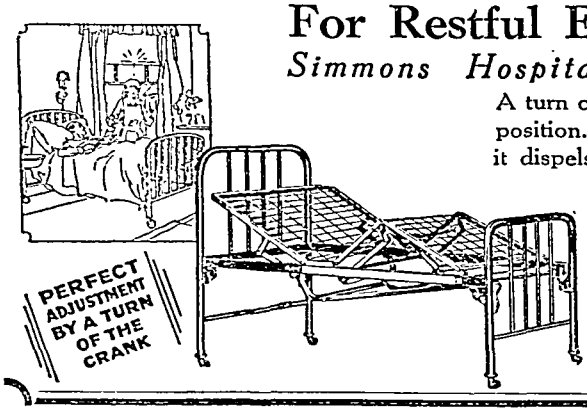
Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

MEDICAL SUPPLY ASSOCIATION Ltd.,

167/185, Gray's Inn Road, LONDON, W.C.1. — 12, Holly Street, SHEFFIELD. — 10/13, Teviot Place, EDINBURGH.

London Telephone: Terminus 5432 (6 lines).



For Restful Ease or Surgical Positions—

Simmons Hospital Beds are instantly adaptable

A turn of the crank adjusts the Simmons Bed into any desirable position. For convalescents this means maximum repose, for it dispels the necessity of constantly rearranging pillows.

The strong construction of Simmons Beds, and their hygienic qualities, make them invaluable to all Hospitals and Institutions.

SIMMONS

Equipment for Hospitals and Institutions

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

FLATULENCE AND ALIMENTARY FETOR

MANY conditions are associated with flatulence, some of which frequently give rise to embarrassment of distant organs.

Dyspepsia, catarrh and ulceration of the stomach and intestine, cancer, dysentery, and other diseases of the alimentary canal itself, neurasthenia, and diseases of the heart, liver and pancreas, to name only a few, may all be associated with flatulence and intestinal flatus.

Some of the diseases of the intestine, such as dysentery and cancer, are often also associated with horrible fetor of the evacuations.

The accumulation of flatus in the stomach and intestine is liable to embarrass the action of the heart and lungs, giving rise to dyspnœa, disordered action of the heart, faintness and even anginal attacks.

Both the flatulence and fetor are the result of abnormal fermentation and putrefaction of the contents of the alimentary canal; apart from treatment of the condition itself, it can be rationally controlled by the use of an efficient intestinal disinfectant. For this purpose, Kerol, the most potent germicide, being unabsorbed and non-toxic, is unsurpassed, and can be safely administered in sufficient amount to exert its germicidal action.

When the fermentation is located in the stomach, KEROL CAPSULES (Gastric) m. 3, should be administered: one or two may be given three or four times a day after meals.

When there is intestinal flatus and fetor, the keratin-coated KEROL CAPSULES m. 3, should be used, the dose being one to three after meals.

Intestinal

Kerol Capsules

STANIFORM

Regd. BRAND. Trade Mark.

OINTMENT METHYL STANNIC IODIDE **LOTION**
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

A anacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists', Sundriesmen or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

West End Clothes

CITY OF LONDON MENTAL HOSPITAL, DARTFORD, KENT.

PRIVATE PATIENTS under certificates and VOLUNTARY PATIENTS are received for treatment at a weekly fee of TWO GUINEAS and upwards.—Apply, MEDICAL SUPERINTENDENT.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS, NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, golf courses, and bowling greens, lawn tennis courts (grass and hard courts), croquet grounds, football and hockey grounds. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL, BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psychotherapeutic treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Billiards, tennis, etc. Fees from five guineas per week.

Telephone: Newport Pagnell 121.

Apply, Dr. D. L. M. DOUGLAS-MORRIS.

HAYDOCK LODGE, NEWTON-LE-WILLOWS, LANCASHIRE.

Phone: 11 Ashton-in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition. Self-supported by its own farm and gardens. Situated in park and grounds of 400 acres. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER, SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.

Telephone: Teignmouth 269.

THE COPPICE, NOTTINGHAM. HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of **Private Patients** of both sexes of the **Upper and Middle Classes** at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117.

For terms, etc., apply to the Medical Superintendent.

RUTHIN CASTLE

(FORMERLY DUFF HOUSE, BANFF)

The first Private Hospital in the United Kingdom to be fully provided with a whole-time specially qualified Staff of Doctors, Analytical Chemists, Bacteriologists, Radiologists, Nurses, Dietists, Masseurs, and Masseuses, and full equipment of Laboratories, X-rays, Electrocardiographs, Artificial Sunlight, and Medical Baths.

The Hospital is equipped for the diagnosis and treatment of any form of ill-health, except Mental and Infectious Diseases. The fees are inclusive.

The climate is mild and the neighbourhood beautiful. Apply: The Secretary,

Telegrams: Castle, Ruthin. Telephone: 66, Ruthin. Ruthin Castle, North Wales.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

THE OLD MANOR SALISBURY

A Private Hospital for the Care and Treatment of those of both sexes suffering from MENTAL DISORDERS.

Extensive grounds. Detached Villas. Chapel. Garden and dairy produce from own farm. Terms very moderate.

(Gower Street, W.C.1.)

Royal London Ophthalmic HOSPITAL (Moorfields Eye Hospital), City Road, London, E.C.1.

GIFFORD EDMONDS PRIZE IN OPHTHALMOLOGY.

The Prize of £100 awarded every two years is offered for the best Essay on a subject dealing with Ophthalmology and involving original work, and is open to any British subject holding a medical qualification.

The subject for the next Essay is:

RADIANT ENERGY AS (*a*) A PATHOGENIC AND (*b*) A THERAPEUTIC AGENT IN OPHTHALMIC DISORDERS.

NOTE.—It is not expected that any candidate will deal comprehensively with all branches of the above subject—a selection should be made.

Preference will be given to original work based on any branch of the subject, rather than to compilations of the writings of previous observers.

Essays must be sent in not later than December 31st, 1932.

A leaflet giving full particulars of the prize may be obtained from the Secretary, Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, London, E.C.1.

London Hospital Medical College.

Borough of Reigate.

MEDICAL OFFICER OF HEALTH, SCHOOL MEDICAL OFFICER, AND MEDICAL OFFICER OF INFANT WELFARE CENTRE.

The Reigate Town Council invites applications from duly qualified persons of not more than 35 years of age, holding a Diploma in Public Health and possessing Municipal or Local Government experience, for the appointment of Medical Officer of Health, School Medical Officer, and Medical Officer of the Infant Welfare Centre for the Borough.

The total commencing salary will be £800 per annum, with an allowance of £40 per annum for travelling and other expenses.

The person appointed will be required to devote his whole time to the duties of his offices, and must reside within the Borough. The duties to be performed are those defined by the Sanitary Officers Order, 1926, made by the Minister of Health, together with any other duties which may from time to time devolve on a Medical Officer of Health by virtue of any present or future Act of Parliament or Orders or Regulations of the Ministry of Health.

He will also be required to act as School Medical Officer and Medical Officer at the Infant Welfare Clinic.

The officer's tenure as Medical Officer of Health will be governed by Section 1 of the Public Health (Officers) Act, 1921.

The Council will provide offices and staff.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be sent, endorsed "Medical Officer," so as to reach me not later than Friday, March 13th next.

Twelve copies of the application and testimonials should also be forwarded for the use of the members of the Committee.

Canvassing in any form is strictly prohibited and will disqualify.

By Order of the Council,
Municipal Buildings, Reigate. ALFRED SMITH, Town Clerk.
February 14th, 1931.

County Council of Middlesex.

DISTRICT MEDICAL OFFICER AND PUBLIC VACCINATOR.

The County Council invites applications from duly qualified Medical Practitioners for the undermentioned appointments:

DISTRICT MEDICAL OFFICER, ISLEWORTH (part of).

Salary £140 per annum, rising by annual increments of £7 10s. to £180 per annum. The officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district, and to name to the Council some duly qualified Medical Practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

PUBLIC VACCINATOR, ISLEWORTH (part of).

The person appointed will be required to produce to the Council a certificate of proficiency in vaccination, unless such certificate was required as a condition of obtaining any diploma, licence, or degree which he possesses.

He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the minimum fees laid down in the Order.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than March 7th.

No special application forms are provided. Envelopes must be endorsed "District Medical Officer" or "Public Vaccinator," as the case may be.

Canvassing, directly or indirectly, will be a disqualification.

Guildhall, Westminster, S.W.1. ERNEST S. W. HART, Clerk of the County Council.
February 10th, 1931.

Borough of Batley.

ASSISTANT MEDICAL OFFICER OF HEALTH (Part-time).

Applications are invited for the above appointment. Candidates must be registered Medical Women possessing the qualifications prescribed by the Ministry of Health, paragraph 7 of the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930. The duties will entail attendance at an Ante-Natal Clinic and Infant Welfare Centres on two afternoons per week. The remuneration will be 1½ guineas per session of two hours in accordance with the B.M.A. scale, plus travelling expenses.

Applications to be sent forthwith to the undersigned.

G. H. PEARCE, Medical Officer of Health.
Medical Officer's Dept., Batley, Yorks.

Salford Royal Hospital.
(265 Beds.)

Applications are invited for the following vacancies, which will occur in the Resident Medical Staff (male) on March 31st next:

Peptalac
REGD.

THE NEW INSTANT PREDIGESTED FOOD

SIX OUTSTANDING ADVANTAGES

1 PEPTALAC is [illegible] the simplest instant a[illegible]

2 PEPTALAC is fool-proof and requires neither technique, skill nor addition of milk. It renders obsolete the method of peptonisation wherein milk had to be held at a temperature 117°F. for 20-30 minutes under carefully controlled conditions.

3 PEPTALAC is guaranteed to have been pancreatised and the essential components of starch and milk proteins broken down to sugars, peptones, and amino-acids. With other methods of peptonisation this cleavage is uncertain and unreliable and the milk which is added is *not predigested.*

4 PEPTALAC is a safe and practically sterile powder. In the old methods of peptonisation, the milk [illegible] genic organisms and practically sterile.

5 PEPTALAC is therefore invaluable for *infants,* the [illegible] milk-preparations made with it.

6 PEPTALAC is pleasing to the most fastidious palates—salt or chocolate may be added for *further flavouring if desired.*

Metatone

A Palatable Vitamin B Reconstructive Tonic

HARDLY a day of a physician's life is passed without one, or more, of his patients requiring a tonic. Metatone is a general tonic particularly suitable for such occasions. In the treatment of general debility, during convalescence, in neurasthenia, anæmia and rickets, after surgical operations and during pregnancy and the period of lactation, Metatone may confidently be prescribed for its reconstructive, restorative and tonic properties.

Metatone is an agreeable fluid combination of vitamin B, nucleinic acid and glycerophosphates, containing in each fluid ounce:—

Vitamin B Extract	10 grains
Nucleinic Acid	2 grains
Calcium Glycerophosphate	4 grains
Potassium Glycerophosphate ...	4 grains
Manganese Glycerophosphate ...	1/2 grain
Sodium Glycerophosphate	2 grains
Strychnine Glycerophosphate ...	1/25 grain

The adult dose of Metatone is one to two teaspoonfuls, three or four times daily, usually after meals.

Supplied in bottles of 8, 16 and 80 fluid ounces.

THE 'ALLENBURYS'
DIABETIC FLOUR

A special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

Further particulars and clinical trial sample will be sent on request.

MOST ACUTE MIDDLE-EAR INFECTIONS

are not attended by mastoiditis; they are accompanied by earache and temperature, which are usually relieved when the drum ruptures, or is incised. ■ Recovery may be hastened and the possibility of infection decreased by hot packs of Antiphlogistine over the mastoid area. ■ By virtue of its thermotherapeutic, hygroscopic and osmotic properties, together with the antiseptic agents entering into its composition, Antiphlogistine will diminish the congestion in the affected area and destroy the bacteria, thereby checking the infectious processes and relieving pain and tension.

New Books and New Editions

KAPLAN'S RADIATION THERAPY

NEW

Dr. Kaplan devotes his entire book to stating briefly the established principles of radiation therapy, and then to detailing extensively the application of those principles to cases. He explains the methods which he has found give results in treating thousands of patients. He gives the technique he uses. He sounds warning notes. He gives an Index of Diseases and their Treatment, wherein are stated for quick reference the dosage, frequency, precautions, management as applied to individual diseases.

Octavo volume of 354 pages, with 227 illustrations. By IRA I. KAPLAN, M.D., Director, Division of Cancer, Department of Hospitals, New York City. Cloth, 27s. 6d. net.

RAND, SWEENY, & VINCENT GROWTH AND DEVELOPMENT OF THE YOUNG CHILD

NEW

This new book on the young child—by three workers representing the fields of parental education, physical growth, and mental growth—brings teachers and students a unified discussion of our modern knowledge of early childhood. For their material the authors have called upon their rich practical experience and the wealth of material at the Merrill-Palmer School.

12mo. of 394 pages, illu , A.B., R.N., Specialist in Parental E M.S., M.A., Nutritionist; and E. I gist, at the Merrill-Palmer School, Cloth, 12s. 6d. net.

WEBSTER'S LEGAL MEDICINE AND TOXICOLOGY

NEW

Dr. Webster takes up all legal aspects of medicine, all those problems which reach courts of law and on which the physician's opinion is frequently demanded. He applies our modern knowledge of medicine and its related sciences to questions concerning the causes of death, the identity of the living and the dead, the results of wounds and injuries of all kinds, life and accident insurance, mental incompetence from various sources, malingering, legitimacy, abortion and infanticide, impotence, sterility, unnatural sexual offences, marriage, divorce, and malpractice. There is a complete section on Toxicology.

Octavo of 862 pages, illustrated. By RALPH W. WEBSTER, M.D., Ph.D., Clinical Professor of Medicine (Medical Jurisprudence) in Rush Medical College, University of Chicago. Cloth, 37s. 6d. net.

CECIL'S TEXT-BOOK OF MEDICINE

2nd EDITION

For this brand new edition the entire book had to be reset, because the 135 eminent contributors were given *carte blanche* in the revision of their articles. The new (2nd) edition represents to-day's approved practice. In addition to the hundreds of changes throughout the book, there are entirely new chapters on tularemia, snake venom poisoning, atelectasis of the lungs, creeping eruption, oroya fever, brucella abortus infections, essential hypertension, agranulocytic angina, and arthritis. In his selection of authors, Dr. Cecil was particularly fortunate. Most of them are teachers in medical schools, and their authoritative presentations are in a form specially acceptable to all those interested in the study and application of medical knowledge.

Octavo of 1,592 pages, illustrated. By 135 American Authors. Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical School. Cloth, 40s. net.

PEARL'S MEDICAL BIOMETRY AND STATISTICS

2nd EDITION

The growing recognition by medical men of the importance of modern biometric methods called forth this new edition. The author's extensive changes and additions have made it even more practical. This work will be of inestimable value to those interested in medicine, public health, biology, statistical research, general hygiene, genetics, life expectation, and epidemiology. It gives methods of collecting, tabulating, adjusting, and drawing sound conclusions.

Octavo of 459 pages, illustrated. By RAYMOND PEARL, Professor of Biology in the School of Hygiene and Public Health, and in the Medical School, The Johns Hopkins University. Cloth, 25s. net.

DACOSTA'S MODERN SURGERY

10th EDITION

A number of unusually practical features have won for "DaCosta" its enduring place in medical literature. Readers and reviewers have termed it "The greatest one-volume surgery ever published"; "A surgical encyclopaedia"; "The work of a master surgeon, a brilliant exponent of modern surgery." Not only does Dr. DaCosta present the principles and practice of surgery, but so carefully does he go into diagnosis that you get a surgical diagnosis as well. The book is an inexhaustible mine of facts for practitioner, surgeon, and specialist.

Octavo of 1,404 pages, with 1,050 illustrations, some in colours. By JOHN CHALMERS DACOSTA, M.D., LL.D., F.A.C.S., Samuel D. Gross Professor of Surgery, Jefferson Medical College. Assisted by BENJAMIN LIPSHUTZ, M.D., F.A.C.S., Surgeon to the Mt. Sinai Hospital, Philadelphia. Cloth, 45s. net.

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta St., London, W.C.2.

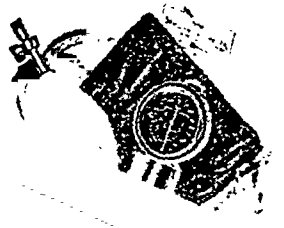
As necessary as a Stethoscope

The present-day physician can ill afford to dispense with a sphygmomanometer as part of his visiting equipment. Many of the greatest medical minds of to-day advocate blood pressure tests as a guide to the eventual diagnosis.

The question of portability is easily solved by the S. & M. Portable type of Sphyg. as illustrated. This instrument—including Patent Arm Sleeve and Inflating Bulb with Control Valve—is contained in a leather carrying case 7 in. long, 4 in. wide by 3 in. deep.

Write for full details and prices.



Every genuine instrument bears the trade-mark "Tycos" engraved on the dial.

Obtainable from all reputable Instrument Dealers.

Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

RE-INFORCING THE ABDOMINAL MUSCLES WITHOUT UNDUE PRESSURE!

For those disorders of the abdomen that call for external support, Domen Abdominal Belts have very definite advantages. They give adequate support to the abdomen without setting up pressure to aggravate the patient's condition. And whether it is pregnancy or umbilical hernia, prolapsus uteri, or simply general support, there is a Domen Belt designed specifically for that condition. Domen Belts fit well, sit comfortably and do not get out of place. They leave the patient free and without embarrassment. Full particulars will be forwarded on receipt of your card or a telephoned request.

When Operation for Hernia is Inadvisable—

A Spencer Abdominal Belt, or Supporting Corset gives excellent Results.

TO be effective a support for hernia must stay in place. Each Spencer support is designed especially to meet the needs of the individual who will wear it. This assures perfect fit and adjustment at all times, since the Spencer support for hernia is non-elastic as well as individually designed.

Spencer hernia supports are comfortable. They fit, and they have no hard rubber or heavy metal parts.

They are also strong and well made, in order to provide both durability and absolute security for the patient.

Spencer supports for reducible umbilical hernia may be prescribed with or without auxiliary pads, according to the patient's need.

For cases of non-reducible umbilical hernia, a special protecting pad used with a Spencer Belt will shield a small hernia of this type from injury, and will prevent increase in the size of the hernia mass. For a very large non-reducible umbilical hernia, the Spencer Belt is made so that the mass is gently but firmly supported, to provide comfort and to guard against increase in the size of the hernia. Inguinal hernia, ventral hernia at the site of an operation scar, can be properly taken care of by a Spencer support.

SPENCER SUPPORTING CORSET

Front unclasped and held back to show the inner supporting section.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue the following booklets on the use of Spencer Supports: Hernia, Sacro-iliac Strain, Enteroptosis and Intestinal Stasis, Movable Kidney, Pregnancy and Postpartum Support. We will gladly send you any of them in which you are interested.
